The strong correlation between the ability of an agent to produce mutations in DNA and its ability to cause cancer suggests that damage to DNA plays a causal role in carcinogenesis. Furthermore, persons with genetic diseases such as ataxia telangiectasia, which is characterized by defects in DNA repair, have an increased risk of dying from cancer. The repair of DNA lesions, especially those induced by UV radiation, is outlined. The induction of lesions in DNA by benzo(a)pyrene is also mentioned. (no refs.)

78-3650 **The Role of Enzymatic DNA Repair in Carcinogenesis and Cancer Chemotherapy.** (Ger) Harbers, E. (Abteilung fur Medizinische Molekularbiologie, Klinisch-Theoretischen Zentrum der Medizinischen Hochschule Lubeck, Ratzeburger Allee 160, D-2400 Lubeck 1, W. Germany). *Z Krebsforsch* 92(1): 1-9; 1978.

The mechanism of DNA repair and the effects of carcinogens and cytostatic drugs on this repair are reviewed. Excision repair of DNA is considered relatively error-free and postreplication repair is considered error-prone. A positive correlation between the binding of benzo(a)pyrene (BP) to DNA and a carcinogenic effect has been shown in animal studies and in human epithelial cell cultures. In the latter, the number of BP molecules bound per unit length of DNA varied 75-fold among cells from different patients. This observation might be used to determine persons at high risk for lung cancer. Cytostatic drugs are relatively weak carcinogens. Inhibitors of DNA repair (caffeine, 2-chlorethyl isocyanate) can increase the effect of alkylating cytostatics. However, tumor production by 4-nitroquinoline 1-oxide is decreased by caffeine, an apparently paradoxical effect. The different biological effects of carcinogens vs cytostatics may result from the ability of the former to cause DNA changes that are hard to repair. In contrast, cytostatics at comparable doses kill many cells and leave others with damage that can be repaired. If these differences could be increased, the late damage from cytostatics would be decreased. The result would be an increased use of these drugs in nonmalignant disease (eg, for immunosuppression). (38 refs.)

78-3651 **Experimental Tumor Metastasis: Characteristics and Organ Specificity.** (Eng) Nicolson, G. L. (Dept. Developmental and Cell Biology, Univ. California, Irvine, CA, 92717). *Bioscience* 28(7): 441-447; 1978.

The characteristics and organ specificity of experimental tumor metastasis are reviewed. Blood-borne metastasis appears to depend on the unique properties of the malignant cell as well as host properties. A successful experimental model of blood-borne metastasis was developed for the murine B16 melanoma. Malignant variant lines (B16-F1 to B16-F10) were selected from the original tumor population for their abilities to implant, invade, survive, and grow to form gross organ tumors after iv injection of B16 cells into C57/Bl mice.

In vivo selection of the B16-F system yielded unique tumor cell lines that were lung-specific trapping in the first capillary bed encountered. In addition, variant lines capable of colonizing different specific secondary sites were obtained using line B16-F1. B16-F1 was retargeted by sequentially selecting for tumor variants that colonize brain, ovary, liver, and other sites from primary sc tumor implants or experimentally administered blood-borne tumor cells. The heterogeneity of the tumor cell properties in the unselected population is probably responsible for the successful in vivo selection of organ-preferring lines. Cell-surface proteins and glycolipids and the adhesive, invasive, enzymatic, and immunological properties of metastatic tumor cells are surveyed using results obtained with the B16-F variants. Protection against experimental metastasis by immunization has been achieved in several animal tumor systems. However, in the B16-F variant system, the host immune response may actually aid in malignant cell arrest and survival. Other aspects of host immunity are reviewed. (54 refs.)

78-3652 **Primary Immunodeficiencies and Malignant Proliferation.** (Fre) Brouet, J. C. (Laboratoire d'Immunochimie et d'Immunopathologie, U. 108 INSERM, Hopital Saint-Louis, 2, place du Dr-Fournier, F 75475 Paris Cedex 10, France); Seligmann, M. *Bull Cancer (Paris)* 65(1): 89-94; 1978.

Reports in the literature reveal that the incidence of neoplasms in persons with primary immune deficiencies (PID) is 100-1,000 times greater than that in the normal population. The incidence of cancer is approx 10%-20% in patients with Wiskott-Aldrich syndrome, 10% in patients with ataxia telangiectasia, and 5%-10% in patients with variable deficiencies; the incidence is $<5\%$ for the other disease categories of PID. A genetic factor is probably involved, since an international cancer registry contains 14 PID families in which 2 or more children developed tumors; in 12/14 families, the tumors were identical. Malignant lymphomas account for two-thirds of all the tumors in patients with PID. Since neoantigens have been demonstrated on only a small number of human tumors, the immunological surveillance theory, which states that abnormal cells are eliminated by the surveillance of immune cells, does not appear feasible. Also, in animals, immunodepression induced by antilymphocyte serum does not increase the incidence of spontaneous tumors. The more likely explanation appears to be antigenic stimulation of a faulty immune system that lacks regulatory controls. (24 refs.)

78-3653 **Transfer of Specific Immunity with RNA.** (Eng) Sell, S. (Dept. Pathology, Univ. California, San Diego, CA); Mendelsohn, J. *Arch Pathol Lab Med* 102(5): 217-222; 1978.

A review of the current status of studies on immune-RNA (iRNA) is presented. iRNA refers to phenol extracts of lymphocytes from immunized animals that have the capacity to transfer a variety of immune products or activities to recipient animals. iRNA from lymphoid cells of immunized or tumor-bearing animals has been found to consistently convert lymphoid cells from nonimmunized humans or animals to killer cells. Positive results have been obtained with syngeneic, allogeneic, and xenogeneic iRNA. Furthermore, iRNA extracted from tumor-immunized guinea pig or sheep lymphoid cells can equip normal human or mouse lymphocytes to kill tumor cells in vitro. It appears that T cells serve both as the source of the iRNA and as the recipient cells. Phase 1 and 2 clinical trials in humans have yet to produce a beneficial effect. More extensive trials are not warranted until more is known about what iRNA is, where it comes from, and what it does. (80 refs.)

78-3654 **Dual Mechanism of Surveillance of Malignant Cells by the Host.** (Ita) Alexander, P. (Div. of Tumor Immunology, Chester Beatty Res. Inst., Belmont, Sutton, Surrey, England). *Recent Prog Med (Roma)* 63(6): 641-648; 1977.

Immune surveillance over malignant cells is reviewed. The significant increase in tumor frequency and distant metastases in immune deficiency states indicates the important role of specific immunity in the control of malignant processes. (7 refs.)

78-3655 **The Radiobiological Significance of the Studies with ^{224}Ra and Thorotrast.** (Eng) Mole, R. H. (Medical Res. Council Radiobiology Unit, Harwell, Didcot, Oxfordshire, OX11 ORD, England). *Health Phys* 35(1): 167-174; 1978.

The results of three large national (Denmark, Portugal, and Germany) surveys of populations injected with Thorotrast (TT, thorium dioxide) are reviewed. In these countries the use of TT stopped 20 yr ago. All three surveys showed a similar excess of liver tumors (3%-8% of the affected population) and leukemia (1%). The pooled observations suggest that other malignant diseases arising in bone marrow (0.8 expected vs 5 observed) and lymphoid tissue (2 expected vs 10 observed) were also increased. Male lung cancer was in excess in Denmark and Portugal, and the combined excess of 8 cases/1,200 men is statistically significant. However, there was no evidence of such an excess in Germany. The risk coefficients on the linear hypothesis for leukemia, lung cancer, and osteogenic sarcoma from TT and other irradiations are compared. The high-risk coefficient for liver tumor induction and the pathology of the TT-bearing liver itself indicate that the convention of averaging dose over a whole organ may be misleading. Local deposits of TT provide sufficient local dose to produce severe local necrosis in this nominally radiation-resistant organ, regeneration in successive cycles could then lead to carcinogenesis. The contribution of localized irradiation by TT deposits to induction of malignant disease in bone marrow and lymph nodes is uncertain. This has to be allowed for if tumor induction in TT subjects is to be understood in terms of translocated daughters of thorium-232, including radium-224. (37 refs.)

78-3656 **Cancer and Trauma.** (Ger) Thomas, C. (Pathologisches Institut, Albertstrasse 19, D-7800 Freiburg, W. Germany); Moehrs, D.; Joachim, H. *Med Klin* 73(36): 1229-1237; 1978.

Literature concerning the theory that trauma leads to cancer is reviewed. In the older literature (1895-1906), it was estimated that about 20% of all tumors were due to by trauma. Increasing knowledge of carcinogenesis biostatistical methods has led to stricter criteria for assigning a causal role to trauma and a lower estimate of trauma-related tumors. The number of sarcomas that developed at the site of old World War I wounds was estimated to be 1/200,000 in 1949. A survey was made of 340 published cases of a connection between trauma and tumor development. The latency time between tumor and trauma varied from 2 wk to 64 yr. The time decreased as the av age of the patient increased. The peak incidence of these 340 tumors was at age 40-60, about 10 yr earlier than that for the general population. When tumors of early adulthood (sarcomas and testicular tumors) were removed from consideration, the peak age was the same as that in the general population. Study of the frequency curves indicated an association between irritating traumas and carcinomas and between blunt traumas and sarcomas. In contrast to the earlier literature, few mammary tumors were reported to be associated with trauma. Instead, it appears that trauma causes patients to find mammary tumors. Repeated trauma may lead to tumors through the action of promoting factors that are released when regeneration occurs. (42 refs.)

78-3657 **Biological Effects of Radiation and Dose-limiting Systems.** (Ita) Commissione Internazionale Per Le Protezioni Radiologiche (International Commission for Radiation Protection, Rimini, Italy). *Radiol Med (Torino)* 64(Suppl 1): 6-26; 1978.

Methods of estimating the risk of cancer development in various organs and tissues due to radiation, particularly low-LET (linear energy transfer) radiation, received at varying rates are reviewed. By calculating dose-response relationships, safe max levels of exposure for humans can be estimated, but these approximations must not be regarded as absolutes. The reproductive organs, hematopoietic system, bones, lungs, and thyroid glands are particularly susceptible to radiation-induced cancer. In Japanese atom bomb survivors, the incidence of leukemia peaked shortly after the time of exposure and finally returned to prebombing levels 25 yr later. It is estimated that the risk of developing leukemia or lung tumors becomes significant at a dose of 2 x 10^{-3} Sievert^{-1} (1 Sievert = 100 rem). Because the amount of radioactivity in the atmosphere varies, it is difficult to estimate the radiation risk for lung tumors in subjects exposed occupationally to radioactive material. There is a higher risk when the radioactive material is inhaled and uniformly distributed throughout the lung. Extensive proposals for limiting radiation doses received therapeutically, occupationally, and by the population at large are outlined. (no refs.)

78-3658 **Radiotherapy for Benign Dermatoses: Indications and Side Effects.** (Ger) Goldschmidt, H. (Suite 620, 1 Bala Cynwyd Plaza, Bala Cynwyd, PA, 19004). *Hautarzt* 29(5): 283-291; 1978.

The use of radiotherapy for benign dermatoses has decreased markedly during the past decades, and the remaining current indications are reviewed. The side effects of ionizing radiation are presented in detail, with special emphasis on radiodermatitis, skin cancer, the mutagenic and genetic effects of x-rays, and cancer of the internal organs. Modern theories of radiocarcinogenesis and risk coefficients of various organ systems are surveyed with the use of thyroid cancer as an example. Guidelines for the radiotherapy of benign dermatoses are proposed. (45 refs)

78-3659 **Hazards of Radiation Exposure for Pregnant Women.** (Eng) Swartz, H. M. (Radiation Biology and Biophysics Section, Dept. Radiology, Medical Coll. Wisconsin, Box 186, Milwaukee, WI, 53226); Reichling, B. A. *JAMA* 239(18): 1907-1908; 1978.

The risk of fetal genetic damage and congenital anomalies and cancer in the children of women irradiated during pregnancy is discussed. Radiation during the first trimester of pregnancy should be avoided, since a large dose (5-15 rads) to the pelvis increases the risk of a congenital anomalies from 1% to 3%. Low doses (0.2 rad) of radiation can increase the risk of a child developing cancer, but this risk is offset by the low risk of cancer (1/1,500) in the first 15 yr of life. Radiation to the gonads should be minimized to prevent mutations that could be passed to progeny. (5 refs.)

78-3660 **The Sensitivity of the Human Breast to Cancer Induction by Ionizing Radiation.** (Eng) Mole, R. H. (MRC Radiobiology Unit, Harwell, Oxon OX11 ORD, England). *Br J Radiol* 51(606): 401-405; 1978.

Evidence that ionizing radiation causes breast cancer in humans is reviewed, and the application of this evidence to practical problems is considered. Several studies have shown an increase in the incidence of breast cancer in women who have undergone multiple fluoroscopy for pulmonary tuberculosis or radiotherapy for nonmalignant diseases of the breast and in survivors of the bombing of Hiroshima and Nagasaki. These studies suggest that the max sensitivity to breast cancer induction by radiation is in women between the ages of 10 and 20 yr, and that this sensitivity may be correlated with hormonally regulated tissue activity. The minimum latent period before induced breast cancer was seen was 10-15 yr for fluoroscopy and radiotherapy and perhaps shorter in the Japanese bomb survivors; induced cases continued to appear, however, for up to 40 yr after exposure. The use of mammography and other diagnostic radiology procedures and occupational exposure and radiological protection are discussed. No recommendations are made about the use of radiotherapy in breast disease or about mammography as a screening procedure to detect early breast cancer. (17 refs.)

78-3661 Experience with Breast Biopsies for Mammographic Findings. (Eng) Cheek, J. H. (Dept. Surgery, Baylor Univ. Medical Center, Dallas, TX). *Breast* 4(1): 4-9; 1978.

Recent experience with breast biopsies performed because of mammographic findings is discussed. During a 7-yr study period, 3,833 new breast examinations were performed. There were 237 cancers among 253 patients biopsied for suspicious clinical and mammographic findings, 60 cancers among 81 patients biopsied for clinical reasons despite negative mammograms, 13 cancers in 13 patients with physical examinations and mammograms indicative of benign lesions, 21 cancers in 21 patients with suspicious clinical findings and no mammograms, and 7 cancers in 7 patients aged < 32 yr with clinical findings indicative of benign lesions and no mammograms. There was no significant difference in the numbers of patients above and below age 50 operated on for mammographic findings, although more cancers were found in patients aged > 50 yr. A majority of the lesions were infiltrating duct cell carcinomas or intraductal carcinomas. Indications for biopsy and mammography and mammographic indications for biopsy are listed. The findings suggest that if there are suspicious clinical and mammographic findings, the lesion is likely to be a carcinoma. (31 refs.)

78-3662 Mammography in Younger Women: The Concern, the Controversy, and the Confusion. (Eng) Frankl, G. (Kaiser-Permanent Medical Center, Los Angeles, CA). *Breast* 4(1): 14-15; 1978.

The concern, controversy, and confusion related to the role of mammography in women <50 yr old are discussed. The concern in younger women is about the hazard of radiation However, the minimal dose of 0.3 rad should not dissuad doctors from performing a potentially life-saving examination. Breast cancer is an important entity in women aged 35-50 yr. One-third of the 708 breast cancers found among 20,214 patients examined by xeromammography at Kaiser-Permanente Foundation Hospital (Los Angeles) occurred in women <50 yr old. Moreover, 31% of all the occult cancers among this population were in younger women. With current equipment and techniques, which allow penetration of young, dense breast tissue, the detection rate for younger women has improved. Recommended indications for performing mammography are given. (no refs.)

78-3663 Adipose Tissue, a Neglected Factor in Aetiology of Breast Cancer? (Eng) Beer, A. E. (Dept. Cell Biology, Univ. Texas Health Science Center at Dallas, 5323 Harry Hines Blvd., Dallas, TX, 75235); Billingham, R. E. *Lancet* 2(8084): 296; 1978.

The adipose tissue in the breast may contribute significantly to the hypersusceptibility of this organ to cancer development by prolonging the duration of exposure of mammary epithelium to lipid-soluble endogenous and environmental carcinogens via a reservoir or depot effect. (8 refs.)

78-3664 Cancer in Old Age. (Eng) Lew, E. A. (No affiliation given). *Ca* 28(1): 2-6; 1978.

In the last decade, new information concerning mortality patterns in the aged population of the US has become available. The 1969-1971 US cancer incidence rates (from the Third National Cancer Survey) and death rates (from the National Center for Health Statistics) for whites aged 75-99 in selected areas are presented. The data are for cancer at all sites and for cancer of the digestive system, respiratory system, prostate, and breast. The incidence and death rates for all forms of cancer tend to increase from age 65 to the late 80's, after which they decline. Elderly patients are frequently reported as dying from intercurrent disease, especially when the symptoms of cancer are silent and metastasis is not apparent. Heart and cerebrovascular diseases are often given preference over cancer as causes of death when both are present. The elderly may constitute a biologically select group that may be relatively insusceptible to cancer, at least insofar as a high proportion of cancer-prone individuals might be expected to have died by age 85. (no refs.)

78-3665 Epidemiology of Gastrointestinal Tumours: A Review. (Eng) McConnell, R. B. (Gastroenterology Unit, Broadgreen Hosp., Thomas Drive, Liverpool L14 3LB, England). *J R Soc Med* 71(4): 278-281; 1978.

The epidemiology of gastrointestinal tumors is reviewed. For different tumors there exists not only a variation between countries, but also a variation within countries, as illustrated by the high occurrence of colon cancer in industrialized countries, except Japan, and the finding that gastric cancer is more common in the lower socioeconomic strata. Incidences tend to change with time, as shown by the dramatic fall in gastric cancer incidence in the US and the less-dramatic fall in Canada. Various epidemiological factors in cancer of the esophagus are outlined. (16 refs.)

78-3666 **The Aetiology of Cancer: Clues from Spontaneous Recovery.** (Eng) Merkin, L. (Dept. Medicine, Roosevelt Hosp., New York, NY). *Med Hypotheses* 4(2): 136-140; 1978.

A review of the literature indicates that several patients, some with highly invasive tumors, survive > 15 yr after standard treatment with no evidence of disease. It is suggested that persons with a long-term disease-free survival be questioned extensively in an attempt to discover some factor, perhaps unique to all, that could have been involved in the origin of the cancer and its cure. (8 refs.)

78-3667 **Genetics of Gastrointestinal Polyposis.** (Eng) Bussey, H. J. (Pathology Dept., Saint Mark's Hosp., City Road, London CE1V 2PS, England); Veale, A. M.; Morson, B. C. *Gastroenterology* 74(6): 1325-1330; 1978.

The types of gastrointestinal polyposis with a possible or proved genetic etiology are (1) the hamartomatous lesions of Peutz-Jeghers syndrome and multiple juvenile polyposis and (2) the neoplastic tumors of familial polyposis coli and multiple adenomas. The mode of inheritance, associated lesions, malignancy potential, and possible interrelationships among these conditions are discussed. The degree of associated malignancy is slight in the Peutz-Jeghers syndrome and juvenile polyposis, but it is definite and strong in familial polyposis coli and multiple adenomas. The knowledge that conditions predisposing to gastrointestinal cancer can be inherited should enable their diagnosis at an early stage. The extent to which cancer prevention can be effective has been shown in the case of familial polyposis. (50 refs.)

78-3668 **Cancer Death Risk in Hospitalized Mental Patients (Letter to Editor).** (Eng) Fox, B. H. (NCI, Bethesda, MD, 20014). *Science* 201(4360): 966-968; 1978.

The statistical methods used in previous studies of the risk of cancer death among hospitalized mental patients are analyzed. In these studies, the mental patients were found to have both lower and higher cancer death rates than those of the general population. Most of these findings can be explained on the basis of whether proportionate or absolute mortality rates were used. Most studies using the latter, more accurate, method have found that the overall cancer mortality in mental patients is greater than that in the general population. (14 refs.)

78-3669 **Genetics and Human Cancers: Methods of Study.** (Fre) Feingold, J. (Groupe de Recherches de Genetique epidemiologique, INSERM, U. 155, Chateau de Longchamp, Bois de Boulogne, F76016 Paris, France). *Bull Cancer (Paris)* 65(1): 73-77; 1978.

The following method of determining the hereditary nature of the common cancers are reviewed: (1) study of twins; (2) familial studies involving statistics on mortality or comparisons of certain groups with cancer and matched controls; (3) interracial studies; (4) studies of the association between genetic markers and cancer incidence. Certain problems arise with the last method, such as whether the presence of a certain gene is simply a predisposing factor rather than an absolute condition for development of a cancer, whether the existence of the gene marker and the cancer in a subpopulation is coincidental or causal, etc. A familial concentration of certain cancers may be due to exposure to a common environment or to the presence of heritable genetic factors. (27 refs.)

78-3670 **Current Assessment of "Case Clustering" of Lymphomas and Leukemias.** (Eng) Smith, P. G. (DHSS Cancer Epidemiology and Clinical Trails Unit, Univ. Oxfordk, 9 Keble Road, Oxford, England). *Cancer* 42(2, Suppl): 1026-1034; 1978.

Data on case clusters of lymphomas and leukemias are reviewed and problems associated with epidemiologic studies of clustering designed to detect a viral etiology are discussed. Many reported case clusters of leukemia and lymphoma are impossible to evaluate statistically, but controlled studies of space-time clustering involving patients with leukemia and Hodgkin's disease (HD) have not yielded convincingly positive findings. Clustering would not be expected, however, if the period between infection and onset were long. A study of childhood leukemia, assuming a possibly long latent period, did not produce evidence of case-to-case transmission. Studies of HD are conflicting: strong evidence of clustering of cases in schools was found in one US study, but a similar British study had negative results. Further studies are necessary to determine whether case-to-case transmission can take place. There is indirect evidence that suggests that HD might arise as a rare response to a common infection. In such circumstances, case clustering of HD would not necessarily be expected to occur. Space-time clustering of Burkitt's lymphoma (BL) has been a distinctive feature of the disease, but it has not been seen in all areas where BL is endemic. In a recent study, patients involved in such clusters were, on the av, older than other patients, which supports the notion that the clustering is a real effect and does not represent an artifact of case ascertainment. Current evidence suggests that most cases of "African" BL arise as a result of an interaction between Epstein-Barr virus infection and chronic severe malaria. If so, it is likely that it is the malaria that precipitates the onset of BL and that clustering of cases is likely to be related with malarial infection. (63 refs.)

78-3671 **Multiple Etiologies of Human Acute Leukemia?** (Eng) Killmann, S. A. (Div. Hematology, Dept. Medicine A, Rigshospitalet, 9, Blegdamsvej, DK-2100 Copenhagen, Denmark). *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 431-435; 1977.

That human acute leukemias have a multiple etiology is suggested in part by geographical differences in chromosome aberrations (trisomy 8) in acute myeloid leukemia (AML) patients. Additional evidence is derived from studies of histocompatibility antigens in black children with AML or acute lymphoblastic anemia (ALL) and studies of WBC group 5 antigens in AML and ALL patients and their families. The monoclonal origin of chronic myeloid leukemia is discussed together with the reported antineoplastic effects of certain virus infections. (14 refs.)

78-3672 **The Biosynthesis of Oncovirus Proteins.** (Eng) Eisenman, R. N. (Fred Hutchinson Cancer Res. Center, Seattle, WA, 98104); Vogt, V. M. *Biochim Biophys Acta* 473(3/4): 187-239; 1978.

The biosynthesis of oncovirus proteins is reviewed with particular emphasis on the biosynthetic steps involved in the regulation of virus growth and how synthesis and modification are related to function. The patterns of oncovirus protein biosynthesis are essentially similar for avian and mammalian viruses, and in each case, the four major internal structural proteins are synthesized from a common *gag* gene precursor. The products of the *pol*, *env*, and *src* genes are also discussed. (385 refs.)

78-3673 **Comparative Epidemiology of Virus-Induced Leukemias.** (Eng) Jarrett, O. (Dept. Veterinary Pathology, Univ. Glasgow, Glasgow, Scotland). *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 11-17; 1978.

The epidemiology of virus-induced leukemias in domestic poultry, cats, and cattle is discussed in relation to its relevance to the study of leukemia and related diseases in other animals, including humans, for which evidence of a viral etiology is still equivocal. Avian leukosis virus (ALV) is common in domestic poultry and is maintained by congenital transmission from persistently infected and viremic hens, through their eggs, to their chicks. Contact transmission of ALV is less important for the maintenance of the virus cycle. Contact and congenital transmission of feline leukemia virus (FeLV) also occurs in cats. The development of FeLV-related disease appears to be related to the degree of contact between infected and uninfected animals and, hence, to the dose of virus. A low dose effectively immunizes the recipient without causing disease, whereas a high dose leads to overt disease. Leukemia in cattle appears to occur in two forms: an enzootic form in which adult multicentric disease is typical and a sporadic form which adolescent thymic or calf multicentric disease is found. A viral etiology of leukemia has been proved in all three species. However, in both cats and cattle, virus-negative cases of leukemia are found, and study of the epidemiology of these leukemias will be needed to determine how they relate to the natural history of FeLV and bovine leukemia virus and how closely they resemble human leukemia. (28 refs.)

78-3674 **Carcinogenesis due to the Type C Oncornavirus. Biological, Immunological and Genetic Aspects.** (Ita) Chieco-Bianchi, L. (Istituto di Anatomia Patologica, Padova, Italy); Collavo, D.; Colombatti, A.; Biasi, G. *Recent Prog Med (Roma)* 63(6): 592-621; 1977.

There is no direct evidence of oncornavirus being the cause of neoplasm formation in humans. However, C-type oncornavirus was isolated from human leukemia and sarcoma cells in culture. (115 refs.)

78-3675 **Viruses and Mammary Neoplasia in Mice and Men.** (Eng) Bentvelzen, P. (Radiobiological Inst. TNO, Rijswijk, Netherlands). *In: Characterization and Treatment of Human Tumours. Proceedings of the Seventh International Symposium on the Biological Characterization of Human Tumours held in Budapest, April 13-15, 1977.* Davis, W.; Harrap, K. R., eds. (Amsterdam: Excerpta Medica): Advances in Tumour Prevention, Detection and Characterization. Vol. 4, 332 pp.; 7-19; 1978.

The role of mammary tumor viruses MTV) in murine breast cancer is reviewed. Particular attention is focused on the properties of murine MTV, their transmission, genetic factors controlling their expression, epigenetic factors involved in their expression, the immunological reactivity of mice to MTV, and the vaccination of mice against mammary tumor development. The viral etiology of murine mammary tumors but not that of human breast tumors, has been proved. MTV sequences have been found in the cellular RNA of human breast cancers, but their role in the human disease is conjectural. If the MTV-related viral genome present in human cellular DNA should be oncogenic to humans, its major influence would be in premenopausal breast cancer cases. (89 refs.)

78-3676 **Common Progenitors in the Evolution of Mammalian Retroviruses: Implications in the Search for RNA Tumor Virus Expression in Man.** (Eng) Aaronson, S. A. (Lab. RNA Tumor Viruses, NCI, Bethesda, MD, 20014); Barbacid, M.; Hino, S.; Tronick, S. R.; Krakower, J. M. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 127-133; 1978.

Information on the distribution and transmission of endogenous C- and D-type mammalian retroviruses is summarized. The evolution of C-type viruses from a common ancestor has been supported by radioimmunoassays of the translational product of the C-type viral genome. Of the known products, structural proteins p30, p15 (p12 of the baboon/RD114 virus group), and p10 and reverse transcriptase contained interspecies antigenic determinants shared by all mammalian C-type viruses isolated to date. Competition radioimmunoassays have also established that endogenous D-type viruses, encompassing isolates of both New and Old World primates, are antigenically and hence genetically related. The application of radioimmunoassays for detecting retrovirus expression in humans is discussed. (26 refs.)

78-2677 **Cell Transformation in Culture and Cutaneous Carcinogenesis.** (Ita) Andreassi, L. (Sienai, Italy). *G Ital Dermatol* 113(1-2): 29-50; 1978.

Human epithelial cell cultures are suitable for studying the neoplastic transformation of cells by papilloma virus and chemical carcinogens and the subcellular mechanisms of transformation. (169 refs.)

78-3678 **Skin Tissue Culture and Verruca and Molluscum Contagiosum Virus.** (Ita) Spagnoli, U. (Siena, Italy); Baiocchi, R. *G Ital Dermatol* 113(1-2): 79-86; 1978.

Human epidermal cell cultures are suitable for the study of cell transformation due to papilloma virus and molluscum contagiosum virus. These viruses are unable to form complete virus particles in the absence of keratinization. (34 refs.)

78-3679 **Fibronectins--Adhesive Glycoproteins of Cell Surface and Blood.** (Eng) Yamada, K. M. (Lab. Molecular Biology, NCI, Bethesda, MD, 20014); Olden, K. *Nature* 275(5677): 179-184; 1978.

The structure, location, and probable functions of fibronectins (FN's), a class of adhesive, high-mol-wt glycoproteins present on the surfaces of cells, in connective tissue matrices, and in extracellular fluids, are reviewed. Cell-surface FN constitutes 1%-3% of the total cellular protein of embryonic or adult fibroblasts cultured in vitro. Most of the FN is present in extracellular fibrils and aggregates. Plasma FN is present in human plasma at 0.3 mg/ml and at a lower concentration in serum. The tumorigenicity of cell lines generally correlates with decreases in cell-surface FN. However, recent studies indicate that decreases in this protein may correlate more with the propensity of the cells to metastasize. Decreases in cell-associated FN after malignant transformation are 5- to 7-fold in chick fibroblasts and > 10-fold in human fibroblasts and glial cells. FN's are thought to be involved in a wide variety of cellular activities, including cell-cell aggregation, cell-substratum adhesiveness, reversion of the transformed phenotype, increased cell motility, reticuloendothelial system clearance of colloids, and specific binding to macromolecules. It is not clear if all of these biological activities are shared by both the plasma and cell-surface forms of FN. In transformed chick fibroblasts and hamster cells, major factors in the loss of FN after transformation appear to be reduced biosynthesis and increased degradation. In human transformants, however, decreased capacity to retain the protein on the cell surface may be more important than decreased synthesis. (175 refs.)

78-3680 **Mutagenic Effect of Aflatoxin B_1.** (Eng) El-Zawahri, M. (Dept. Genetics, Assiut Univ., Assiut, Egypt); Moubasher, A.; Morad, M.; El-Kady, I. *Ann Nutr Aliment* 31(4/5/6/): 859-866; 1977.

The mutagenic effect of aflatoxin B_1 on human peripheral blood lymphocytes was investigated. Aflatoxin B_1 induced a high rate of nonrandom chromosome breaks and interchanges. A highly significant number of breaks were selectively induced on chromosomes 2, 11, 19, and 20. The high breakage rate was accompanied by an increase in sister chromatid exchanges. (14 refs.)

78-3681 **Morphological Observations of Aflatoxin-induced Liposis in Rat Hepatocytes.** (Eng) Kendall, M. W. (Dept. Anatomy, Sch. Medical Sciences, 1 Manville Medical Sciences Building, Univ. Nevada, Reno, NV, 89557). *Chemosphere* 7(8): 625-632; 1978.

Light and electron microscope studies were made of hepatocytes from male weanling Fischer rats fed aflatoxin B_1 (AFB) in order to determine the cell organelle alterations of AFB-induced liver toxicity, particularly the accumulation of lipid. Rats were fed Purina rat chow with or without the addition of 4.0 ppm AFB. Animals were killed and their livers prepared for histological study at the end of every 3 mo for 15 mo. AFB-treated animals were also sacrificed on day 1. At the end of 15 mo, 12/20 rats fed AFB had hepatocellular carcinomas. No fatty metamorphosis, lipid accumulation, or tumors were observed in livers from control rats over the 15 mo period. Lipid was observed in the periportal hepatocytes in 18/20 AFB-fed rats sacrificed at 3 mo, although it probably occurred much earlier. Electron microscope study of these hepatocytes revealed myelin figures and lipid vacuoles with numerous vesicles of smooth endoplasmic reticulum (SER). The lipid may have originated in the SER vesicles. The accumulation of lipid in the hepatocytes did not seem to increase with duration of treatment. Centrilobular hepatocytes were not affected by AFB. It is concluded that the cytoplasmic lipid accumulations in the periportal hepatocytes probably reflect nucleolar biochemical alterations that eventually lead to hepatoma. (17 refs.)

78-3682 **Epidemiological Features of the Mycotoxicoses.** (Eng) Akkmeteli, M. A. (Div. Noncommunicable Diseases, World Health Organization, Geneva, Switzerland). *Ann Nutr Aliment* 31(4/5/6): 957-976; 1978.

Several features associated with the outbreak of mycotoxicoses in man and animals are presented. The possible role of mycotoxins in endemic nephropathy in some East European countries and liver disease in Mongolia is discussed. It is suggested that these two diseases, as well as stachybotryotoxicosis and alimentary toxic aleukia, have common epidemiological features, but in the former two, these features are spread out over a long period of time. The toxic and carcinogenic metabolites of fungi are believed to play important roles in these diseases. (40 refs.)

78-3683 **Transmission of Aflatoxin B_1 into the Tissues of Growing Pigs.** (Eng) Jacobson, W. C. (Bureau Veterinary Medicine, Food and Drug Admin., Beltsville, MD, 20705); Harmeyer, W. C.; Jackson, J. E.; Armbrecht, B.; Wiseman, H. G. *Bull Environ Contam Toxicol* 19(2): 156-161; 1978.

The levels of aflatoxin B_1 (AFB) and aflatoxin M_1 (AFM) in the tissues of pigs fed diets containing 100, 200, or 400 μg AFB/kg feed were determined. Appreciable amounts of AFB were found in tissue samples of animals fed all three diets; measureable amounts of AFM were found in all specimens except two (both muscle). Liver tissue had no evidence of pathologic damage. Mathematical analysis indicated a linear relationship between the logs of AFB intake and the amounts of residues in the tissues. (10 refs.)

78-3684 **Inhibition of Mitochondrial DNA Synthesis by Aflatoxin B_1 and Dimethylnitrosamine.** (Eng) Friedman, M. A. (Allied Chemical Corporation, P.O. Box 1021R, Morristown, NJ, 07960); Bailey, W.; Van Tuyle, G. C. *Res Commun Chem Pathol Pharmacol* 21(2): 281-294; 1978.

The acute and subchronic effects of aflatoxin B_1 (AFB) and dimethylnitrosamine (DMN) on mouse liver mitochondrial DNA synthesis were determined using male C3H/He mice. In single acute injection experiments, mice received 20 mg/kg of the test carcinogen ip and were killed 16 hr later. In the subchronic experiments, mice received a weekly injection of 0.16 mg DMN or 0.23 mg AFB. During the week of sacrifice, these mice received an extra dose of AFB 2 days after their regular injections and they were killed 18 hr later. At 10, 20, 30, and 40 min after a single injection of AFB, labeled thymidine (TdR) uptake by mitochondrial DNA was inhibited to 49%, 46%, 42%, and 46% of the control uptake, respectively. This inhibition appeared to represent a general inhibition of DNA synthesis together with loss of replicative intermediates. After a single injection of DMN, TdR uptake was inhibited to 24%, 54%, 59%, and 51% of control, respectively. As with AFB-treated mice, incorporation into high-mol-wt mitochondrial DNA was markedly inhibited, the effect on low-mol-wt mitochondrial DNA synthesis was less marked. After 5 wk of AFB treatment, TdR uptake was inhibited to 45%, 56%, 48%, and 51% of controls at incubation times of 10, 20, 30, and 40 min, respectively. With DMN, the respective inhibition was 68%, 72%, 72%, and 70% of controls. After 13 wk of AFB treatment, the AFB diet, inhibition of mitochondrial DNA synthesis at incubation times of 10, 20, 30, and 40 min was 51%, 46%, 41%, and 47% of controls. The synthesis of high-mol-wt DNA was decreased to the same extent as gross TdR uptake. The respective figures for DMN were 46%, 50%, 37%, and 46% of controls. However, in DMN-treated mice, there appeared to be a uniform inhibition of TdR incorporation that appeared to be greater in magnitude than that suggested by gross TdR incorporation. (12 refs.)

78-3685 **Trout Hepatic Enzyme Activation of Aflatoxin B_1 in a Mutagen Assay System and the Inhibitory Effect of PCBs.** (Eng) Stott, W. T. (Dept. Food Science and Technology, Oregon State Univ., Corvallis, OR, 97331); Sinnhuber, R. O. *Bull Environ Contam Toxicol* 19(1): 35-41; 1978.

Optimal conditions for use of the Ames assay with rainbow trout (*Salmo gairdneri*) liver postmitochondrial fraction (PMF) were defined using aflatoxin B_1 (AFB) as the test compound. In addition, the effect of several polychlorinated biphenyl (PCB) compounds on the response of the assay to AFB was investigated. The experiments clearly indicated the ability of fish liver drug-metabolizing enzymes to function in the Ames mutagen assay. Optimal mutagen assay conditions were obtained with 6.4 mg PMF protein and 160 nanograms AFB/incubation mixture and a metabolic incubation temperature of 25 C. A significant increase in the number of revertants was observed when metabolic incubations were performed at 25 C for 9 hr. When the fish were pretreated ip with 500 mg/kg of Aroclor 1242, Aroclor 1254, or Aroclor 1260, there was a significant reduction in the assay response vs the control response. This result was in contrast to the results of assays using rat PMF. The mutagen assay response with fish PMF decreased with increasing chlorination of the PCB's, which may reflect the ability of PCB's as inducers of these enzyme systems in rainbow trout. This finding appears to substantiate recent findings in rainbow trout feeding trials of Aroclor 1254 and AFB in which PCB-treated fish had a lower AFB-induced incidence of cancer. (30 refs.)

78-3686 **Aflatoxicosis in Swine.** (Eng) Hayes, A. W. (Dept. Pharmacology and Toxicology, Univ. Mississippi Medical Center, Jackson, MS, 39216); King, R. E.; Unger, P. D.; Phillips, T. D.; Hatkin, J.; Bowen, J. H. *J Am Vet Med Assoc* 172(11): 1295-1297; 1978.

Necropsy studies of several pigs from a herd in which 30/250 had died within 1 mo indicated that they had aflatoxicosis. Histiopathologic findings were characteristic of experimentally induced aflatoxicosis, and aflatoxin B_1 (AFB_1) was found in the serum. AFB_1 and AFB_2 were found in the feed corn. Combine harvesting, which cracks the kernels, plus a prolonged drying time probably contributed to the AFB production. (15 refs.)

78-3687 **Aflatoxicol: Major Aflatoxin B_1 Metabolite in Rat Plasma.** (Eng) Wong, Z. A. (Dept. Environmental Toxicology, Coll. Agricultural and Environmental Sciences, Univ. California, Davis, CA, 95616); Hsieh, D. P. *Science* 200(4339): 325-327; 1978.

Aflatoxicol (AFL), a carcinogenic metabolite of aflatoxin B_1 (AFB), was identified as the major aflatoxin metabolite in the plasma of Sprague-Dawley rats, a susceptible species, that had been dosed po (3.0 mg/kg) or iv (1.0 mg/kg) with ^{14}C-AFB. AFL, however, was not detected in the plasma of similarly dosed mice and monkeys, which are resistant to AFB-induced carcinogenesis. The formation of AFL both in vitro and in vivo may be an indicator of species sensitivity to AFB-induced carcinogenesis and may be useful in the prediction of human susceptibility. (26 refs.)

78-3688 **The Effects of Asbestos-Cement Dust Inhalation on Baboons.** (Eng) Goldstein, B. (Natl. Res. Inst. Occupational Diseases, South African Medical Res. Council, P.O. Box 4788, Johannesburg, S. Africa); Webster, I.; Rendall, R. E.; Skikne, M. I. *Environ Res* 16(1/3): 216-225; 1978.

Twelve male baboons (*Papio ursinus*) were exposed for 266-444 days to dust collected from an extraction system in the hard-sheet cutting section of an asbestos-cement factory. The sheets were composed of 12% asbestos (1.2% crocidolite and 10.8% chrysotile) and 88% cement. The exposure sessions were 7 hr/day, 5 days/wk. The mean fiber count of the dust was 166 fibers/cm^3 and the respirable dust concentration was 17.7 mg/m^3. The length of the fibers ranged from 5 to 100 μm, and 80% of the cement particles were < 10 μm. By 266 days, the animals developed lung fibrosis that was morphologically similar to asbestosis. In all cases, asbestos fibers and dust particles were noted in the fibrotic areas. There were also occasional ferrunginous bodies. Two animals, exposed for 266 and 441 days, respectively, also developed atypical metaplasia of the bronchiolar epithelium, and a bronchiolo-alveolar carcinoma could not be excluded. (5 refs.)

78-3689 **Hemolytic Action of Asbestos.** (Fre) Vaille, C. (69, boulevard de Beausejour, 75016 Paris, France); Souchard, M. *Ann Pharm Fr* 36(1/2): 23-32; 1978.

In vitro, Canadian, Corsican, and Rhodesian chrysotile asbestos caused hemolysis in human and rat blood. The South African amosite and crocidolite forms of asbestos did not produce this effect, and the degree of hemolysis due to Finnish anthophyllite was only one-third that due to chrysotile asbestos. In vivo, hemolysis can be measured by the amount of bilirubin in the bile after iv injection of various types of asbestos. Iv injection of the three chrysotiles, crocidolite, and amosite into Wistar CF rats caused hemolysis, but anthophyllite did not. Inhalation exposure of the rats to chrysotile aerosols did not produce a hemolytic effect. (20 refs.)

78-3690 **Malignant Mesothelioma and Gas-Mask Assemblers.** (Eng) Jeffreys, D. B. (Guy's Hosp., London SE1 9RT, England); Vale, J. A. *Br Med J* 2(6137): 607; 1978.

The case histories of two employees of gas mask assembly plants who developed malignant mesothelioma are presented. In each case, the employees had worked on masks with filters containing asbestos. The first was an 83-yr-old woman who developed mesothelioma 63 yr after exposure during the first world war and the second was a 62-yr-old man who developed the disease 37 yr after exposure during the second world war. (5 refs.)

78-3691 **Familial Mesothelioma after Intense Asbestos Exposure at Home.** (Eng) Li, F. P. (Clinical Studies Section, Clinical Epidemiology Branch, NCI, 35 Binney St., Boston, MA, 02115); Lokich, J.; Lapey, J.; Neptune, W. B.; Wilkins, E. W. *JAMA* 240(5): 467; 1978.

Pleural mesotheliomas occurred in the wife and daughter of an asbestos handler, indicating that gross asbestos contamination of the home may be a hazard. The father, who had worked as a pipe insulator in a shipyard from 1940 to 1965, was diagnosed at age 60 with pulmonary asbestosis. He died at age 71 due to metastatic adenocarcinoma in the upper left lobe of the lung. He also had been a heavy cigarette smoker for several decades. The mother and daughter, who experienced no occupational exposure to asbestos, developed right pleural effusions at ages 50 and 34, respectively. Thoractomy/thoracentesis and pleural biopsy specimens revealed the mesotheliomas. The daughter's tumor had a biphasic or mixed pattern of epithelial-type cells with papillary formations, glandlike spaces, and spindle cell metaplasia. The mother's tumor was similar in appearance but with more extensive fibrosis. Two younger daughters were found to be free of cancer. During World War II and several years thereafter, the father had experienced intensive exposure to asbestos insulation dusts, which covered his work clothes. He brought these asbestos-covered clothes into the home. As no other source of asbestos exposure was identified, asbestos pollution of the home is considered a cause of cancer in the mother and daughter. Contributing factors may include a genetic susceptibility to cancer in this family and the early age of exposure in the daughter. (3 refs.)

78-3692 **Asbestos Exposure and Cancer of the Larynx.** (Fre) Bianchi, C. (Institut d'anatomie et histologie pathologique, l'Universite de Trieste, Trieste, Italy); Di Bonito, L.; Castelli, M.; Brollo, A. *Pathologica* 70(1005/1006): 403-408; 1978.

Exposure to asbestos and use of tobacco (in cigarettes) were compared in 60 patients (58 men, 2 women) who underwent laryngectomy (LG) for epidermoid carcinoma of the larynx and in 60 sex- and age-matched controls who were hospitalized for noncancerous diseases. The LG patients ranged in age from 30 to 89 yr, but most were aged 40-69 yr. Some patients had laryngeal surgery as long ago as 22 yr, but most had been operated after 1970. Fifty-eight of the LG patients were smokers vs 44 controls. The difference between the two groups in av daily number and total number of cigarettes smoked was significant ($p < 0.02$); but not the difference in duration of smoking habit. There was also no significant difference ($p < 0.1$) in the number of LG patients and controls exposed to asbestos. Four LG patients and three controls had a history of heavy exposure; otherwise, the degree of exposure could not be determined. There was a history of exposure to other respiratory irritants (gas, smoke from soldering operations and combustion) that frequently coincided with asbestos exposure in 40 LG patients and 35 controls. A combination of exposure to asbestos and smoking habit was more frequent ($0.05 < p < 0.07$) in the LG group. (19 refs.)

78-3693 **Hazards of Inorganic Arsenic (Letter to Editor).** (Eng) Nurse, D. S. (71 Mayston St., E. Hawthorne, Victoria 3123, Australia). *Med J Aust* 1(2): 102; 1978.

A 45-yr-old man developed an adenocarcinoma of the kidney 17 yr after cessation of 5-yr of inorganic arsenic treatment for psoriasis. One year prior to diagnosis of the renal tumor, a basal cell carcinoma was removed from his neck. It is suggested that the arsenic played a significant role in the development of the renal carcinoma. (1 ref.)

78-3694 **Occupational and Environmental Risks in and Around a Smelter in Northern Sweden. II. Chromosomal Aberrations in Workers Exposed to Arsenic.** (Eng) Nordenson, I. (Dept. Medical Genetics, Univ. Umea, S-901 85 Umea, Sweden); Beckman, G.; Beckman, L.; Nordstrom, S. *Hereditas* 88(1): 47-50; 1978.

The frequency of chromatid aberrations was investigated in smelter employees with high, medium, and low exposure to arsenic, newly employed persons (most of whom lived near the smelter), and controls. A significantly increased frequency in aberrations was found in all employees compared with controls; however, the correlation between frequency of aberrations and As exposure was rather poor, probably because of individual susceptibility and a proposed cocarcinogenic action of As with cigarette smoking. As may inhibit DNA repair of aberrations caused by other agents. (9 refs.)

78-3695 **Urothelial Hyperplasia of the Urinary Bladder of the Rat Induced by Mechanical Perforation and Phenacetin Treatment.** (Eng) Johansson, S. (Dept. Pathology II, Sahlgren's Hosp., 413 45 Goteborg, Sweden). *Acta Pathol Microbiol Scand (A)* 86(4): 333-335; 1978.

The combined effects of mechanical trauma and phenacetin treatment on the urinary bladder were studied in male Sprague-Dawley rats. Twelve rats were subjected to mechanical perforation of the bladder (with a 23-gauge needle) and dietary phenacetin (0.535%). Four rats received phenacetin only, four perforation only. Rats from each group were sacrificed at 1, 2, and 3 wk after treatment, and the bladder and kidneys were examined histologically. Eleven of the twelve rats given the combined treatment developed urothelial hyperplasia. In two of the rats, the entire bladder mucosa was involved. All of the rats subjected to perforation alone or phenacetin treatment alone had a normal bladder mucosa. The renal pelvis and papillae of all rats appeared normal. It was not possible to determine whether the urothelial hyperplasia was reactive or preneoplastic. (8 refs.)

78-3696 **Mutagenic Effect of Orally Given AF-2 on Embryonic Cells in Pregnant Syrian Hamsters.** (Eng) Inui, N. (Dept. Experimental Pathology, Cancer Inst., Japanese Foundation Cancer Res., Toshima-ku, Tokyo 170, Japan); Nishi, Y.; Taketomi, M. *Mutat Res* 57(1): 69-75; 1978.

The mutagenic effect of 2-(2-furyl)-3-(5-nitro-2-furyl)acrylamide (AF-2) was studied in hamster embryo cells. Syrian golden hamsters were given 2, 5, 10, 50, or 100 mg/kg AF-2 by gastric intubation on the 11th or 12th day of pregnancy, and their fetuses were excised 24 hr later. Cells were isolated from the embryos and cultured in normal medium. Chromosome preparations were made within 24 hr after the start of primary culture. Marked chromosomal abnormalities were observed in cells from embryos of animals treated with >20 mg/kg AF-2. Samples of surviving cells were also cultured in normal medium for 48 hr and then selected in medium containing 8-azaguanine (8AG) or 6-thioguanine (6TG). AF-2 treatment caused a marked dose-dependent induction of 8AG- or 6TG-resistant mutations; mutant colonies were even obtained after a single treatment with 2 mg/kg AF-2. It is concluded that this mammalian system is sensitive and useful for detecting environmental mutagens. (19 refs.)

78-3697 **Mutagenicity of Acrylonitrile.** (Eng) De Meester, C. (Lab. Analytical Chemistry, Univ. Louvain, Sch. Pharmacy, U.C.L.-73.69, B. 1200 Brussels, Belgium); Poncelet, F.; Roberfroid, M.; Mercier, M. *Toxicology* 11(1): 19-27; 1978.

Incubation of several *Salmonella typhimurium* strains in an atmosphere of 0.2% gaseous acrylonitrile increased the number of cells that underwent a reversion to histidine prototrophy only in the presence of a fortified postmitochondrial (S_9) liver fraction. The mutagenic effect was particularly marked with strains TA1530, TA1535, and TA1950 and was much weaker with strains TA100, TA98, and TA1978. The results of bacterial fluctuation tests confirmed the absence of a direct mutagenic effect of AN and the particular sensitivity of strain TA1530 can the presence of the S_9 mix. The mutagenicity of AN in *S. typhimurium* is this microsome-mediated and is optimal with strains sensitive to base-substitution mutagens. Studies of the effect of the composition and origin of the S_9 mix showed that 300 μl S_9/ml mix and a mouse origin produced the highest numbers of revertants per plate. Liver fractions from Arochlor 1254- or 3-methylcholanthrene-treated rats produced the greatest mutagenic effects, followed by those from butadiene- and styrene-treated rats. (18 refs.)

78-3698 **Trapping and Determination of Labile Compounds in the Gas Phase of Cigarette Smoke.** (Eng) Zeldes, S. G. (Analytical Chemistry Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Horton, A. D. *Anal Chem* 50(6): 779-782; 1978.

Adsorption-gas chromatographic techniques that allow the trapping and recovery of all the isoprene and acrolein and 80% of the acetaldehyde in the gas phase of cigarette smoke are presented. Optimum conditions for the adsorption and desorption of the gas phase and the effects of aging on the trapped gases were also determined. (9 refs.)

78-3699 **Induction of 6-Thioguanine Resistance in Human Cells Treated with N-Acetoxy-2-acetylaminofluorene.** (Eng) Huang, S. L. (Lab. Environmental Mutagenesis, Natl. Inst. Environmental Health Sciences, P.O. Box 12233, Research Triangle Park, NC, 27709); Lieberman, M. W. *Mutat Res* 57(3): 349-358; 1978.

Induction of 6-thioguanine resistance was studied in human fibroblasts treated with the direct-acting chemical carcinogen N-acetoxy-2-acetylaminofluorene (NA-AAF). At low

NA-AAF concentrations (2.5 to 7.5 μM), induction of resistant clones was linear and followed one-hit kinetics. At 10 μM, some higher order function appeared to be involved. Only 2.5 to 3.0 of every 10,000 NA-AAF molecules bound at the hypoxanthine-guanine phosphoribosyltransferase (HGPRT) locus resulted in detectable mutations. Fifty mutant colonies were evaluated for growth in 6-thioguanine-containing medium. About 12% of the clones had low ($<8\%$ of wild-type) HGPRT activity and showed poor ability to grow in hypoxanthine plus azaserine (HAs) medium. Most of the other clones had 25% to 80% as much HGPRT activity as wild-type cells and grew in HAs medium. There was no correlation between the NA-AAF concentration used to induce the mutations and the enzymatic activity or growth characteristics of the cells. The data suggest that most bound acetylaminofluorene molecules either produce no change in the primary DNA sequence or result in changes that are phenotypically undetectable. (17 refs.)

78-3700 **Induction of Sister-Chromatid Exchanges in Mammalian Cells by Low Concentrations of Mutagenic Carcinogens that Require Metabolic Activation, as well as by Those that Do Not (Meeting Abstract).** (Eng) Wolff, S. (Lab. Radiobiology and Dept. Anatomy, Univ. California, San Francisco, CA); Takehisa, S. *Mutat Res* 53(2): 284-285; 1978. (no refs.)

78-3701 **Dietary Lipid-dependent Activation of the Carcinogen N-2-Fluorenylacetamide in Rats as Monitored by *Salmonella typhimurium*.** (Eng) Castro, C. E. (Dept. Food and Nutrition, Texas Tech Univ., Lubbock, TX, 79409); Felkner, I. C.; Yang, S. P. *Cancer Res* 38(9): 2836-2841; 1978.

Salmonella typhimurium TA1538 was used to quantify the ability of tissue homogenate supernatants to activate the carcinogen N-2-fluorenylacetamide (FAA) and the proximate carcinogen N-hydroxy-2-fluorenylacetamide (N-OH-FAA). The supernatants were obtained from male Sprague-Dawley rats fed a basal diet supplemented with 5% or 20% beef tallow (bt) or corn oil (co) for 6 mo and given ip injections of FAA (10 mg/100 g) or of the control vehicle. During the feeding period, animals were given seven injections, the first at the end of week 2 and the remaining at weekly intervals during weeks 7-12. After only 21 days of feeding and one injection of FAA or control vehicle, elevated activity of the liver microsome-free supernatant (S-150) enzyme that converts N-OH-FAA to mutagen was dependent upon the kind and level of dietary fat. Enzyme activity from FAA-treated rats fed 5% co was three times higher than it was in FAA-treated animals fed 5% bt, whereas in FAA-treated animals fed 20% co, enzyme activity was two times higher than it was in rats fed 20% bt. After 6 mo, the mutagen-producing potential of S-150 was increased, regardless of the diet. However, FAA injections plus 20% co or bt promoted the greatest enzyme activity, suggesting a synergistic effect of high fat and FAA. The ability of S-150 to activate potentially mutagenic compounds was 22-fold higher in FAA-treated rats fed 20% co than in FAA-treated animals fed 20% bt. Between 21 days and 6 mo, hepatic enzyme activity increased 2-fold for rats fed 5% bt or co, 5-fold for rats fed 20% bt, and 52-fold for animals fed 20% co. Lung and kidney S-150 activities were assayed with the bacterial system after 6 mo. Dietary fat did not affect the lung activity, and although kidney enzyme activity was increased from one- to threefold, it was less responsive to diet than liver. After 21 days and one FAA injection, rat had a greater concentration of urinary N-OH-FAA glucuronide when fed co than when fed bt. After 6 mo, the urine of rats fed 20% co and given seven injections of FAA exhibited the greatest amount of urinary N-OH-FAA. (40 refs)

78-3702 **Effect of Sodium Selenite and Methyl Methanesulfonate or *N*-Hydroxy-2-acetylaminofluorene Co-exposure on Sister-Chromatid Exchange Production in Human Whole Blood Cultures.** (Eng) Ray, J. H. (Medical Genetic Center, Univ. Texas Graduate Sch. Biomedical Sciences, P.O. Box 20334, Astrodome Station, Houston, TX, 77025); Altenburg, L. C.; Jacobs, M. M. *Mutat Res* 57(3): 359-368; 1978.

The effect of sodium selenite (Na_2SeO_3), alone and combined with methyl methanesulfonate (MMS) or N-hydroxy-2-acetylaminofluorene (N-OH-AAF), on the frequency of sister chromatid exchanges (SCE's) in human whole blood cultures was studied. Mitotic figures were reduced or eliminated by exposure to 3.95×10^{-6} or 7.90×10^{-6} M Na_2SeO_3 for 96 hr, but exposure to 1.19×10^{-5} M for 19 hr did not alter the mitotic index. The higher Na_2SeO_3 concentrations resulted in overall SCE frequencies of 20.71 and 21.51, respectively; these frequencies were significantly elevated compared with background frequencies (6-7 SCE's/cell). Approx 30 SCE's/cell were found in cells exposed to 1×10^{-4} M MMS for the final 19 hr of culture. In cultures exposed to Na_2SeO_3 plus MMS, decreasing MMS:Na_2SeO_3 ratios resulted in SCE frequencies that were 25%-30% below the sum of the SCE frequencies produced by the individual compounds. Exposure of lymphocytes to 2.7×10^{-5} N-OH-AAF resulted in 13.61 SCEs/cell, and exposure to Na_2SeO_3 plus N-OH-AAF resulted in SCE frequencies produced by the individual compounds. (39 refs)

78-3703 **Bladder Carcinogenesis Using Bilharzia-infested Swiss Albino Mice.** (Eng) El-Aaser, A. A. (Dept. Cancer Biology, Cancer Inst., Cairo Univ., Cairo, Egypt); Hassanein, S. M.; El-Bolkainy, M. N.; Omar, S.; El-Sebai, I.; El-Merzabani, M. M. *Eur J Cancer* 14(6): 645-648; 1978.

The role of liver injury and mechanical irritation of the bladder mucosa in the production of bladder cancer was studied in female Swiss albino mice. Liver injury was induced by infecting the mice with *Schistosoma mansoni* (bilharzia, B) or by feeding them 2-naphthylamine (2-NA, 1%) or 2-acetylaminofluorene (2-AAF, 0.06%) in their diet. One group of mice was given indole (1%) in the diet. Bladder irritation was induced by inserting glass beads into the lumen of the bladder to mimic the passage of ova. Liver injury, bladder irritation, and indole treatment were given alone or in various combinations. Mice with liver injury induced by B and/or the hepatocarcinogens did not develop bladder tumors. Furthermore, mice receiving indole alone or with B infection did not show any change in the bladder mucosa. However, the insertion of glass beads into the bladder induced carcinomas in 8/30 mice by 70 wk. This tumor induction was enhanced by 2-AAF (10/25 mice), but not by B infection (5/20), 2-NA (5/18), or indole (6/22). All urinary bladders containing the beads showed evidence of bacterial infection (*Escherichia coli* and gram-positive cocci) and epithelial hyperplasia and metaplasia. (17 refs)

78-3704 **Sequential Alkaline Phosphatase Changes in Hyperplastic and Neoplastic Urothelium of Mice Fed 2-Acetylaminofluorene.** (Eng) Highman, B. (Div. Pathology Services, Natl. Center Toxicological Res., Jefferson, AR, 72079); Frith, C. H.; Littlefield, N. A. *Environ Pathol Toxicol* 1(3): 223-231; 1978.

Histologic and enzymatic changes in the urinary bladders of 430 BALB/c mice fed a stock diet containing 0, 100, or 500 ppm of 2-acetylaminofluorene (2-AAF) were studied. After 12 wk of receiving 500 ppm 2-AAF, nearly all mice showed bladder epithelial hyperplasia with an epithelial decrease and a stromal increase in alkaline phosphatase (AP). There were frequently many cytoplasmic vacuoles, with eosinophilic inclusions often staining like AP, in the superficial polypoid and upper intermediate epithelial cell layers. After 2-AAF withdrawal at 12 wk, these changes decreased, but 1/4 female mice and 2/4 male mice sacrificed at 51 wk had papillary transitional cell carcinomas. Carcinomas were found in all mice receiving 500 ppm 2-AAF continuously for 51 wk or longer. Mice on 100 ppm 2-AAF developed similar changes more slowly. At 57 wk, epithelial changes were moderate or were marked in nearly all males,and they decreased only slightly after the withdrawal of 2-AAF at 54-57 wk. In females, cytoplasmic vacuolation and other changes were milder,and they virtually disappeared at 67 wk (13 wk after withdrawal of 2-AAF). At 57-103 wk,no females on 100 ppm 2-AAF developed carcinomas, whereas nearly all males, even after the withdrawal of 2-AAF at 54-57 wk, developed papillary carcinomas. There appeared to be some correlation between the severity and persistence of cytologic damage, evidenced by vacuoles with inclusions, in a given treatment group and the later development of carcinomas in that group. Invasive tumors were found only after prolonged administration of 500 ppm 2-AAF, whereas papillary tumors were generally found in mice given 500 ppm 2-AAF for only the first 12 wk or in those given 100 ppm 2-AAF continuously or for a limited period. Invasive tumors generally lacked or showed relatively little AP and showed no vacuoles or inclusions, whereas papillary carcinomas often contained abundant AP, suggesting a possible correlation between the degree of invasiveness or malignancy and the degree of enzymatic and morphologic dedifferentiation. (6 refs)

78-3705 **Distribution of α-Fetoprotein- and Albumin-containing Cells in the Livers of Fischer Rats Fed Four Cycles of N-2-Fluorenylacetamide.** (Eng) Sell, S. (Dept. Pathology, Univ. California at San Diego, La Jolla, CA, 92093). *Cancer Res* 38(9): 3107-3113; 1978.

The immunofluorescent localization of α-fetoprotein (AFP)- and albumin-containing cells was determined in the livers of Fischer rats fed 0.05% N-2-acetylfluorenamide for four 2-wk-on, 1-wk-off cycles. After this exposure, multiple changes in the liver included > 1,000 neoplastic nodules/liver, as well as extensive production of oval cells and focal zones of atypical hepatocellular hyperplasia. Approx 1% of the oval cells contained AFP and about half of the zones of atypical hyperplasia included cells that contained AFP, but none of the neoplastic nodules or normal hepatocytes had any AFP-containing cells. Since up to 60% of the hepatocellular carcinomas developing from this regimen will predictably produce AFP, it is tentatively concluded that hepatocellular carcinoma may arise not only from premalignant neoplastic nodules but also from oval cells or the atypical differentiation of hepatocytes. (32 refs)

78-3706 **Disturbances in the Lipid Regulation of Hepatic Microsomal Enzyme Activity During Chemical Carcinogenesis.** (Rus) Burlakova, E. B. (Inst. Chemical Physics, Moscow, USSR); Dzhaliabova, M. I.; Kobliakov, V. A.; Koliada, A. Iu.; Molochkina, E. M. *Dokl Akad Nauk SSSR* 241(2): 477-480; 1978.

To evaluate the effect of chemical carcinogenesis on the regulation of cellular metabolism, random-bred mice were fed a diet containing 2-acetylaminofluorene (2-AAF) or diethylnitrosamine (DENA). Rats treated with 2-AAF were sacrificed after 4-9 wk (first liver tumors appeared during week 12) and rats treated with DENA were sacrificed after 5-27 wk) (first tumors appeared during week 26). The intensity of the free-radical oxidation in the microsomal lipids was measured by the antioxidative activity (AOA) of the lipids. In control rats, the increase in AOA was correlated with a decrease in phosphatidylcholine (PC) and an increase in phosphatidylethanolamine (PEA), but in rats exposed to the carcinogens, the increase in AOA was associated with an increase in PC and a decrease in PEA. (13 refs)

78-3707 **Cotton Rat Anomaly.** (Eng) McGregor, D. B. (Inveresk Res. International, Inveresk Gate, Edinburgh, Scotland). *Nature* 274(5666): 21; 1978.

2-Acetylaminofluorene (AAF) is more efficiently activated to a mutagen detectable by *Salmonella typhimurium* TA1538 if the postmitochondrial supernatant (S-9) is derived from cotton rat liver rather than Wistar rat liver. However, carcinogenicity tests show that AAF may be noncarcinogenic in cotton rats, but it is a potent carcinogen in rats. Although induced liver enzymes may give different results, mutation frequencies obtained with induced liver S-9 are concluded to be less important to quantitative correlations between mutagenesis and carcinogenesis than results with normal liver S-9. (3 refs)

78-3708 **Effects of Chronic Feeding of 2-Acetylaminofluorene on Nuclear Populations in Rat Liver.** (Eng) Irving, C. C. (Cancer Res. Lab., Veterans Admin. Hosp., Memphis, TN, 38104); Roszell, J. A.; Fredi, J. L. *Adv Enzyme Regul* 16: 365-377; 1978.

The effects of chronic 2-acetylaminofluorene (2-AAF) feeding on the liver nuclei of male and female Sprague-Dawley rats were investigated. Male rats were fed 0.04% 2-AAF in the diet and killed at weekly intervals for 6 wk. Liver nuclei were separated into two fractions: one sedimenting through 2.3 M sucrose (class N-I) and another sedimenting through 1.6 M but not 2.3 M sucrose (N-II). During 2-AAF administration, the percentage of DNA found in N-I nuclei decreased from the control value of 86% to 68% by 2 wk and to 1.4% by 3 wk; it then fluctuated between 10% and 40% at 4-6 wk. Corresponding increases were noted in the amounts of DNA recovered in N-II nuclei. These changes occurred in the absence of any appreciable change in net liver DNA content. The ploidy of the nuclei in the fractions was determined by examining nuclei pelleting in 2.3 M sucrose (H nuclei) and nuclei sedimenting through 1.6 and 1.8 M sucrose and banding at the 1.8-2.3 M interface (L nuclei). In normal adult rat liver, the H and L fractions appeared equivalent to the N-I and N-II nuclei, respectively, but in younger animals, the L fraction predominated. The percentage of L nuclei decreased as the animals grew. Both H and L nuclei contained diploid, tetraploid, and octaploid nuclei, but the degree of ploidy was greater in the H fraction. As the percentage of L nuclei decreased with age, the degree of polyploidy in the H fraction increased, suggesting that the shift of nuclei from the L to the H fraction was associated with hepatocyte maturation. Male and female rats were fed 2-AAF and killed at weekly intervals for 12 wk. By 6 wk, the amount of nuclei in the H and L fractions had changed from 75% and 25%, respectively, to 3% and 97%, respectively. The degree of polyploidy in the livers of male rats decreased during the initial 6 wk from 40%-50% to 20%. Alterations in the nuclear populations in the livers of female rats (which are resistant to 2-AAF-induced cancer) were minimal. (25 refs)

78-3709 **Changes in Monoamine Oxidase, Adenylate Cyclase, and Adenosine Triphosphatase Activity in Rat Liver Mitochondria During Hepatocarcinogenesis.** (Rus) Gurkalo, V. K. (N. N. Petrov Res. Inst. Oncology, Leningrad, USSR); Tret'iakov, A. V. *Vopr Med Khim* 24(4): 495-499; 1978.

Changes in liver mitochondria monoamine oxidase (MAO), adenylate cyclase (AC), and ATPase activity were studied during 2-acetylaminofluorene (AAF)- or diethylnitrosamine (DENA)-induced hepatocarcinogenesis in random-bred albino rats. Three histological stages of hepatocarcinogenesis were identified: Stage 1 was characterized by structural rearrangements in the liver tissue (proliferation of embryonal precursors of biliary cells after exposure to AAF and proliferation of atypical hepatocytes after exposure to DENA), Stage 2 by the development of benign tumors, and Stage 3 by the development of cholangiocarcinomas (after AAF) or hepatocellular carcinomas (after DENA). During AAF-induced carcinogenesis, there was trace ATPase activity during Stage I, but during Stage 2, ATPase activity was 50% of the normal value; MAO activity increased markedly from Stage 1 to Stage 3. During DENA-induced carcinogenesis, AC activity remained unchanged during Stage 1, doubled in Stage 2, and showed a progressive decrease (up to 40%-50% of the normal value) during Stage 3. (10 refs)

78-3710 **Quantitative Kinetics of Development of N-2-Fluorenylacetamide-induced, Altered (Hyperplastic) Hepatocellular Foci Resistant to Iron Accumulation and of Their Reversion or Persistence Following Removal of Carcinogen.** (Eng) Williams, G. M. (Naylor Dana Inst. Disease Prevention, American Health Foundation, 1 Dana Road, Valhalla, NY, 10595); Watanabe, K. *J Natl Cancer Inst* 61(1): 113-121; 1978.

The kinetics of development of N-2-fluorenylacetamide (FAA)-induced, iron-free altered (hyperplastic) hepatocellular foci in inbred F344 rats was studied. Iron deposition was induced by feeding the animals a diet (diet 1) containing 0.8% 8-hydroxyquinoline (HQ) and 2.19% ferrous gluconate (FG) for 3 mo. The rats were then fed a diet 1 supplemented with 0.02% FAA for 13 wk, after which they were returned to diet 1. Groups of rats were killed at weekly intervals during the 13-wk carcinogen-feeding period and at 4, 12, and 24 wk after discontinuation of FAA. The absence of iron storage by altered cells was a sensitive marker that permitted the identification of extremely small lesions within 3 wk of carcinogen treatment. These lesions grew in size and number until 13 wk, by which time all lesions corresponded to one of the types of recognized, altered (hyperplastic) foci. They also displayed abnormal glycogen storage. After FAA was discontinued, the foci disappeared by a reversion back to iron storage while temporarily retaining the nuclear abnormalities of altered cells. More than 95% of altered foci underwent reversion by 6 mo following removal of FAA. More advanced lesions developed in the lobes that displayed the greatest incidence and persistence of foci. The behavior of foci at the stage delineated in this study corresponds closely to previously made generalizations for precancerous lesions. (32 refs)

78-3711 **Influence of DDT on the Hepatotoxicity of 2-Acetylaminofluorene in Wistar Rats.** (Pol) Syrowatka, T. (Zaklad Toksykologii Sanitarnej, Panstwowy Zaklad Higieny, ul. Chocimska 24, 00-971 Warsaw, Poland); Jurek, A.; Nazarewicz, T. *Rocz Panstw Zakl Hig* 29(1): 57-64; 1978.

The effect of the simultaneous administration of 1,1,1-trichloro-2,2-bis(p-chlorophenyl)ethane (DDT) and 2-acetylaminofluorene (2-AAF) on the intensity of neoplastic changes in the liver of Wistar rats was determined. In a 9-mo experiment in which animals were given 2-AAF and/or DDT by gastric intubation, no neoplastic changes were noted in the liver. Two groups of animals were then fed 2-AAF (300 mg/kg diet or 2-AAF + DDT (50 mg/kg diet) for 3 mo and then maintained on a standard diet for 10 mo. Histological examination of the liver, kidneys, spleen, and lungs showed neoplastic changes in both groups. However, a much higher mortality was observed among the animals receiving 2-AAF only. The intensity of the neoplastic changes was slightly higher in all the 2-AAF-treated rats, and animals in this group had metastases to various organs. These findings indicate that DDT, at the dose administered, does not augment 2-AAF-induced carcinogenesis, but rather appears to reduce it. (14 refs)

78-3712 **Sacrococcygeal Teratoma in a Neonate. Association with Maternal Use of Acetazolamide.** (Eng) Worsham, G. F. (Dept. Lab. Medicine, Natl. Naval Medical Center, Bethesda, MD, 20014); Beckman, E. N.; Mitchell, E. H. *JAMA* 240(3): 251-252; 1978.

The occurrence of a sacrococcygeal teratoma in an infant born to a mother treated with acetazolamide (AAA) is reported. The mother (22-yr-old) was admitted at 27 wk gestation with spontaneous rupture of the membranes. She had been treated with AAA (750 mg/day) since the age of 13 for glaucoma. AAA therapy was discontinued at 19 wk gestation. The infant had a large tumor in the sacrococcygeal area that was a multilobulated, irregular mass of solid elements: tissue resembling brain, opalescent gray-white cartilaginous tissue, loops of small bowel, mineralized foci, and clotted blood. Histologically, the tumor was composed of tissue from all three germ layers, with a preponderance of neuroectodermal derivatives. Several congenital abnormalities, but not teratomas, have been associated with the use of AAA in gestating experimental animals. This is the third known case of infant morbidity associated with this drug. (5 refs)

78-3713 **In Vivo Somatic Mutation Systems in the Mouse (Meeting Abstract).** (Eng) Russell, L. B. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830). *Mutat Res* 53(2): 255; 1978. (no refs)

78-3714 **Mutagenicity Screening of Feed Additives in Microbial Systems (Meeting Abstract).** (Eng) Shirasu, Y. (Inst. Environmental Toxicology, Kodaira, Tokyo 187, Japan); Moriya, M.; Kato, K. *Mutat Res* 53(2): 261; 1978. (no refs)

78-3715 **Diphenylhydantoin as an Inducer for the Salmonella Mutation Assay.** (Jpn) Shimizu, H. (Dept. Public Health, Jikei Univ. Sch. Medicine, Tokyo 105, Japan); Takemura, N.; Hayashi, K. *Jpn J Ind Health* 19(4): 202-203; 1977.

The effectiveness of diphenylhydantoin (DPH) as an inducer of Sprague-Dawley rat liver microsome drug-metabolizing enzymes for the Salmonella mutation assay was compared with that of polychlorinated biphenyl (PCB), phenobarbital (PB), and 3-methylcholanthrene (3-MC). The order of effectivenss of PCB $>$ PB, DPH $>$ 3-MC. (7 refs)

78-3716 **Is Phenobarbital Carcinogenic? A Follow-up of 8078 Epileptics.** (Eng) Clemmesen, J. (Danish Cancer Registry, Natl. Anti-Cancer League, Strandboulevard 49, Copenhagen 2100, Denmark); Hjalgrim-Jensen, S. *Ecotoxicology and Environmental Safety* 1(4): 457-470; 1978.

A total of 4,268 men and 3,810 women admitted to a Danish epilepsy center from 1933 to 1962 were followed to December 1972 or to their deaths by population files and a nationwide cancer registry to determine if treatment with the anticonvulsant phenobarbital (PB) increases the risk of cancer. PB was given in individual doses of 100-300 mg, mainly in the evening. Phenylhydantoin was given in daytime doses of 100-400 mg, and primidone was administered in doses of 0.5-1.5 g. Separate tables of data were constructed for patients observed $<$ 10 yr and $>$ 10 yr. Besides the expected excess of brain tumors, 11 cases of liver cancer occurred among patients observed $>$ 10 yr vs an expectant number of 2.1. However, eight of these patients had received thorium dioxide for angiography. One of the eight also developed leukemia. There was no excess of leukemia or lymphoma or cancer at any other sites. (37 refs)

78-3717 **Isolation and Structure Studies of Mutagenic Principles in Amino Acid Pyrolysates.** (Eng) Kosuge, T. (Shizuoka Coll. Pharmacy, Shizuoka, Japan); Tsuji, K.; Wakabayashi, K.; Okamoto, T.; Shudo, K.; Iitaka, Y.; Itai, A.; Sugimura, T.; Kawachi, T.; Nagao, M.; Seino, Y. *Chem Pharm Bull (Tokyo)* 26(2): 611-619; 1978.

The mutagenicity of the pyrolysis products of various amino acids was investigated using *Salmonella typhimurium* strains TA98 and TA100. The basic fractions from pyrolysate of DL-tryptophan, L-ornithine, L-glutamic acid, L-serine, L-lysine, creatine, and creatinine were mutagenic toward TA98. Two active agents in the tryptophan pyrolysate were 3-amino-1,4-dimethyl-5H-pyrido-[4,3-b]indole and 3-amino-1-methyl-5H-pyrido[4,3-b]indole. 2-Amino-5-phenylpyridine, benzo[f]quinoline, and phenanthridine were among the mutagenic antimicrobial tar constituents. (11 refs)

78-3718 **Mutagenic and Recombinogenic Effects of the Antitumor Antibiotic Anthramycin.** (Eng) Hannan, M. A. (Coll. Pharmacy, Univ. Kentucky, Lexington, KY, 40506); Hurley, L. H.; Gairola, C. *Cancer Res* 38(9): 2795-2799; 1978.

Anthramycin (AM), a pyrrolo(1,4)benzodiazepine antibiotic with potent antitumor activity, was tested for its effects on histidine reversion in *Salmonella typhimurium* and on forward and reverse mutations, mitotic crossing-over, and gene conversion in *Saccharomyces cerevisiae.* AM was not mutagenic in *S. typhimurium*; it was antimutagenic in three *S. cerevisiae* strains and mutagenic in one. However, AM induced mitotic crossing-over, mitotic gene conversion, and, possibly, other chromosomal alterations in a diploid strain of *S. cerevisiae.* These studies emphasize the need for a battery of test systems, including eukaryotic organisms, to detect the genetic activity of certain antitumor drugs. The importance of considering data that distinguish between highly and weakly mutagenic cancer chemotherapeutic agents is also discussed. (23 refs)

78-3719 **Potential Carcinogens Tested by Induction and Mutagenesis of Prophage λ in *Escherichia coli* K12.** (Eng) Moreau, P. (Section de Radiobiologie, Laboratoire d'Enzymologie, C.N.R.S., 91190 Gif-sur-Yvette, France); Devoret, R. *In: Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation.* Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book C), 583 pp., 1451-1472; 1977.

A test for possible carcinogens based upon lysogenic induction, ie, the induction of prophage λ in *Escherichia coli*, is described. The test is designed so that mutagenesis of prophage λ can be scored independently of lysogenic induction. Thus, it can be determined whether a chemical induces mutagenesis, lysogenic induction, or both. It is felt that a chemical that induces both is a potential carcinogen. Treated λ lysogens in the latent period are plated onto GT-amp plates with 2.5-3 ml of soft agar and with 0.2 ml of indicator bacteria GY4015 at about 2 x 10^9 cells/ml. The plates are incubated overnight at 37 C; ampicillin is added to the GT medium because this antibiotic prevents the noninduced bacteria from multiplying and releasing phage during the overnight incubation. However, ampicillin does not inhibit the induced lysogens from forming infective centers. The efficiency of lysogenic induction is calculated as the ratio of the number of induced infective centers to the number of original viable lysogens. Three variations of this simple, efficient, and inexpensive test are described: a qualitative spot test, a quantitative test on plates, and a quantitative test in liquid medium. The test is as sensitive as mutagenicity tests, and a good correlation was found between the carcinogenic activity of chemicals and their inducing activity. (56 refs)

78-3720 **Comparative Mutagenicity and Toxic Effects of 2,5,2′,5′,-Tetrachlorobiphenyl and Its Metabolites in Bacterial and Mammalian Test Systems.** (Eng) Hsia, M. T. (Dept. Entomology, Univ. Wisconsin, Madison, WI, 53706); Lin, F. S.; Allen, J. R. *Res Commun Chem Pathol Pharmacol* 21(3): 485-486; 1978.

The possible toxicological properties of 2,5,2′,5′-tetrachlorobiphenyl (TCB), 4-hydroxy-2,5,2′,5′-tetrachlorobiphenyl (TCB-OH), and 2,5,2′,5′-tetrachlorobiphenyl-3,4-oxide (TCB oxide) were evaluated in three bioassay systems. Incubation of rat hepatocyte plasma membranes with 50 μg/ml TCB-OH decreased the activity of Mg^{2+}-ATPase by 90%, whereas approx half of the enzyme activity remained after TCB or TCB oxide treatment. All three compounds were found inactive in the *Salmonella typhimurium*/microsome mutagenicity assay. Only TCB-OH possessed potent cytotoxic activity against all four *S. typhimurium* strains tested. It affected the viability of strain TA1537 by as much as 40% even at concentrations as low as 1 μg/ml. These data suggest the potential toxicological significance of PCB phenolic metabolites and of metabolic activation by the hepatic microsomal mixed-function oxidases. (24 refs)

78-3721 **Mutagenic Activity of Chemicals Identified in Drinking Water (Meeting Abstract).** (Eng) Simmon, V. F. (Stanford Res. Inst., Menlo Park, CA); Kauhanen, K.; Mortelmans, K.; Tardiff, R. *Mutat Res* 53(2): 262; 1978. (no refs)

78-3722 **Role of Metabolic Activation in Azide Mutagenesis (Meeting Abstract).** (Eng) Nilan, R. A. (Program Genetics and Dept. Agronomy and Soils, Washington State Univ., Pullman, WA, 99164); Kleinhofs, A. *Mutat Res* 53(2): 242; 1978. (no refs)

78-3723 **Efficiency of Short-Term Tests for Evaluating Mutagenicity of Environmental Chemicals.**

(Rus) de Serres, F. J. (Natl. Inst. Environmental Health Sciences, Research Triangle Park, NC). *Genetika* 14(6): 935-946; 1978.

The effectiveness of the short-term *Salmonella typhimurium* assay for estimating the mutagenicity and, in view of the proposed correlation between mutagenicity and carcinogenicity, the carcinogenicity of various chemicals was evaluated. Of 175 known carcinogens tested, 157 showed mutagenic activity, and of 108 noncarcinogens, only 14 were mutagens. Since the assay may yield false-positive results, tests should also be made in other systems, including eukaryotic cells. (19 refs)

78-3724 **Purification and Characterization of an Endonuclease from *Micrococcus luteus* That Acts on Depurinated and Carcinogen-modified DNA.** (Eng) Hecht, R. (Institut fur Biochemie, Deutsches Krebsforschungszentrum, Im Neuenheimer Feld 280, D-6900 Heidelberg 1, W. Germany); Thielmann, H. W. *Eur J Biochem* 89(2): 607-618; 1978.

An endonuclease (EN) from *Micrococcus luteus* that is capable of recognizing DNA damage induced by methyl methanesulfonate and heat/acid treatment was purified 500-fold and characterized in order to discover which types of DNA damage are handled by which repair enzymes. The purification, achieved by chromatography on phosphocellulose + gel filtration on Sephadex G-50, produced an EN (peak A, or EN-A) that was separate from pyrimidine dimer-specific UV EN (peak B). The mol wt of EN-A was 30,000 daltons. EN-A was not absolutely dependent on divalent cations, but 5-30 mM Mg^{2+} produced a fivefold stimulation of activity. KCl concentrations < 100 mM were optimal, but those > 100 mM inhibited EN-A activity. The enzyme had no effect on native DNA, but it caused single-strand breaks in DNA containing apurinic/apyrimidinic sites produced by heating at an acidic pH. Carcinogen-modified DNA was also susceptible to the action of this enzyme. EN-A activity was detected by making use of the difference in mobility between supercoiled closed-circular DNA of *Pseudomonas* phage PM2 and its nicked form in agarose gel electrophoresis. Even depurinated or carcinogen-modified supercoiled PM2 DNA migrated faster than the respective nicked forms. EN-A introduced approx twice as many breaks into carcinogen-modified PM2 DNA as the number of apurinic sites present. It is concluded that EN-A either recognizes both apurinic sites and DNA bases carrying carcinogenic residues or, more likely, that it contains DNA glycosidase activity in addition to EN activity. Upon exposure to UV-irradiated PM2 DNA, EN-A did not act on pyrimidine dimers but it did act on apyrimidinic sites and on minor photoproducts that may be 5,6-saturated pyrimidine residues. (52 refs)

78-3725 **Comparative Studies of 14 Mutagenic or Carcinogenic Substances in Seven Mutagenicity Test Systems (Point Mutation Tests, Cytogenetic Test and the Dominant Lethal Test) (Meeting Abstract).** (Eng) Muller, D. (Res. Dept., Pharmaceuticals Div., Ciba-Geigy Ltd., Basel, Switzerland); Arni, P.; Fritz, H.; Langauer, M.; Strasser, F. F. *Mutat Res* 53(2): 235; 1978. (no refs)

78-3726 **Crankcase Oils: Are They a Major Mutagenic Burden in the Aquatic Environment?** (Eng) Payne, J. F. (Fisheries and Marine Service, Newfoundland Biological Station, St. John's, A1C 1A1 Newfoundland, Canada); Martins, I.; Rahimtula, A. *Science* 200(4339): 329-330; 1978.

Fractions from used crankcase oil enriched in polyaromatic hydrocarbons (PAH) were mutagenic in *Salmonella typhimurium* strain TA98 when activated by rat or trout liver extracts. The mutagenic activity was not due to benzopyrene or benzanthracene. Fractions from various crude and refined petroleums were nonmutagenic. The results establish that fish can produce mutagenic metabolites from PAH and that used crankcase oils, which are released into the terrestrial and aquatic environment in considerable quantities, may represent a considerable mutagenic threat. (18 refs)

78-3727 **Activation of Carcinogens and Mutagens by Rat Colon Mucosa.** (Eng) Fang, W. F. (Dept. Biochemistry and Molecular Biology, Univ. Texas Medical Sch. at Houston, P.O. Box 20708, Houston, TX, 77025); Strobel, H. W. *Cancer Res* 38(9): 2939-2944; 1978.

Colon mucosal cells can catalyze the activation of precarcinogens to mutagenic metabolites without the intermediacy of intestinal bacteria as, shown in a mutagenesis assay system composed of *Salmonella typhimurium* strain TA100 and the 9,000 x *g* supernatant fraction of rat colon mucosal cells. Pretreatment of rats with β-naphthoflavone increased the activation of 2-aminoanthracene (AA) 10- to 20-fold and the activation of benzo(a)pyrene (BP) 4-fold. Pretreatment of rats with Aroclor 1254 doubled the activation of AA over control levels but had no effect on the activation of BP. The activation of AA and BP by liver was induced significantly by pretreatment with both β-naphthoflavone and Aroclor 1254. Phenobarbital/hydrocortisone pretreatment did not increase the activation by the colon system of any precarcinogen tested, but it did increase the activation of AA, cyclophosphamide, and isophosphamide by the liver system. The activation of precarcinogens in the bacterial test system was directly correlated with the activities of the pretreated colon and liver preparations toward several drug and polycyclic hydrocarbon substrates assayed in vitro. (39 refs)

78-3728 **Metabolism and DNA Binding of Polycyclic Aromatic Hydrocarbons by Human Diploid Fi-**

broblasts. (Eng) Baird, W. M. (Wistar Inst. Anatomy and Biology, 36th St. at Spruce, Philadelphia, PA, 19104); Diamond, L. *Int J Cancer* 22(2): 189-195; 1978.

The metabolism of benzo(a)pyrene (BP), 3-methylcholanthrene (3-MC), and 7,12-dimethylbenz(a)anthracene (DMBA) was measured in mid- and late-passage cultures (population-doubling levels of 20-39 and > 55, respectively) of WI-38 human diploid fibroblasts. Cultures re-fed with 30 ml median containing 0.1 nanomole/ml ^{3}H-hydrocarbon for 144 hr metabolized the hydrocarbons to water- and organic solvent-soluble derivatives. Seven-day-old cultures of late-passage cells metabolized similar amounts of BP and 3-MC as mid-passage cells, but only about one-third as much DMBA per cell. The DNA adducts formed from BP were examined by chromatography of enzyme-degraded DNA samples on Sephadex LH20 columns. On columns eluted with methanol-water gradients, the ^{3}H-BP-deoxyribonucleoside adducts eluted in the same volume as the product peak isolated from DNA that had been reacted with 7,8-dihydroxy-9,10-epoxy-7,8,9,10-tetrahydro-BP. On columns eluted with borate-containing methanol-water gradients, 62% of the cellular products eluted in the same volume as the product peak isolated from DNA that had been reacted with (±)-7α,8β-dihydroxy-9β,10β-epoxy-7,8,9,10-tetrahydro-BP (anti-isomer) and 35% eluted in the same volume as the product peak isolated from DNA that had been reacted with (±)-7α,8β-dihydroxy-9α,10α-epoxy-7,8,9,10-tetrahydro-BP (syn- isomer). The fact that the adducts eluted as two peaks on borate-containing gradients suggests that two isomeric BP-diol epoxides are involved in the binding of BP to DNA in WI-38 cells. (36 refs)

78-3729 **Malignant Transformation of a Mouse Epithelial Cell Line with Polycyclic Aromatic Hydrocarbons.** (Eng) Mondal, S. (Los Angeles County-Univ. Southern California, Comprehensive Cancer Care Center, 1303 N. Mission Road, Los Angeles, CA, 90033); Sala, M. *Nature* 274(5669): 370-372; 1978.

A new epithelial cell line, MC 3T3 [developed from wild mouse (*Mus musculus castaneous*) embryos] that can be transformed by polycyclic aromatic hydrocarbons is described. The cells are polygonal, with a large nucleus and prominent nucleolus, and they grow in compact colonies before they reach confluence. The cells were fed with medium containing 3-methylcholanthrene (3-MC) at 5 or 2.5 μg/ml, benzo(a)pyrene (BP) at 2.5 μg/ml, or 7,12-dimethylbenz(a)anthracene (DMBA) at 1 μg/ml. With each passage, piled-up areas of more refractile cells of various sizes increased in size and number in all the carcinogen-treated dishes. Within 3 to 4 wk, all nude mice injected with 3-MC-, BP-, and DMBA-treated cells developed progressively growing local tumors at the site of injection. The tumors were histologically identified as poorly differentiated carcinomas. (14 refs)

78-3730 **Comparison of the Effects of Beeswax:Trioctanoin and Trioctanoin Vehicles on 3-Methylcholanthrene, Benzo(a)pyrene, and 7,12-Dimethylbenz(a)anthracene Subcutaneous Carcinogenesis in Three Strains of Mice and One Hybrid.** (Eng) Whitmire, C. E. (Toxicology Branch, Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NCI, Landow Building., Room 3C25, NIH, Bethesda, MD, 20014); Lopez, A. *J Natl Cancer Inst* 61(4): 1107-1111; 1978.

The relative carcinogenic effects of 3-methylcholanthrene (3-MC), benzo(a)pyrene (BP), and 7,12-dimethylbenz(a)anthracene (DMBA) suspended in trioctanoin and in a 1:1 beeswax:trioctanoin (B:T) vehicle were compared. Sc tumor induction with 37.5, 150, or 600 μg of each compound/0.1 ml vehicle was studied in C3H/Anf Cum, C57BL/6 Cum, DBA/2J, and (C57BL x C3H/Anf)F$_1$ (BC3F$_1$/Cum) mice. Median tumor dose levels were significantly lower when the three carcinogens were suspended in trioctanoin. When B:T was used as a vehicle, the three carcinogens differed in their abilities to be absorbed or solubilized from the vehicle by the three strains of mice and the hybrid. In C3H/Anf mice, BP in B:T failed to produce tumors. In BC3F$_1$ mice, no tumors were produced by 3-MC, BP, or DMBA in B:T. In C57BL/6 mice, no tumors were produced with DMBA or 3-MC in B:T. In DBA/2 mice, no tumors were produced by BP or 3-MC in B:T. These results indicate that the interpretation of tumor induction results obtained with B:T may be related to the conditions of bioassay rather than to the carcinogenic potential of a compound. 78-3731 **Effect of Prostaglandins on Skin Tumorigenesis.** (Eng) Lupulescu, A. (Wayne State Univ., Medical Res. Building, 550 E. Canfield Ave., Detroit, MI, 48201). *Experientia* 34(6): 785-788; 1978.

The effect of prostaglandins E$_2$ (PGE$_2$) and F$_2\alpha$ (PGF$_2\alpha$) on skin tumors induced by 3-methylcholanthrene (3-MC) was studied in male albino Swiss mice. Mice were treated with 2 ml of a 0.4% acetone soln of 3-MC and/or 10 μg PGE$_2$ or 10 μg PGF$_2\alpha$ im 3 x/wk for 2 mo. Multiple and large squamous cell carcinomas occurred in 90% of the 3-MC and PGE$_2$- or PGF$_2\alpha$-treated mice at the site of 3-MC treatment. No tumors were observed in mice treated with 3-MC or PG only. There was a marked increase (15- to 20-fold) in the incorporation of ^{3}H-thymidine followed by ^{3}H-uridine, ^{3}H-proline and ^{3}H-leucine, in homogenized material from tumors of mice treated with 3-MC + PG compared with the incorporation found in mice treated with 3-MC or PG only or in the control mice. Only epidermal cell hyperplasia with papillary projections protruding in the dermis were visible in 3-MC-treated mice. The results indicate that PGF$_2\alpha$ and PGE$_2$ markedly stimulate DNA, RNA, protein synthesis in hyperplastic epidermal cells following 3-MC application. This may explain the enhancement of cutaneous carcinogenesis by PG's and their shortening of the tumor latency period.

hus, PG's may act as cocarcinogens and have important nplications in cutaneous carcinogenesis. (9 refs)

8-3732 **Accelerated Growth of Syngeneic Tumors in Mice Treated with Methylcholanthrene.** (Eng) ill, P. H. (Cancer Biology Program, NCI Frederick Cancer es. Center, Frederick, MD, 21501); Jessup, J. M.; Kripke, 1. L. *Int J Cancer* 21(4): 511-515; 1978.

he occurrence of selective immunosuppression following reatment with methylcholanthrene (MC) was studied in 3H-, AKR, C57BL, and BALB/c mice. MC was given as single sc injection (1 or 0.05 mg), and the mice were examied at various times thereafter for immunologic reactivity nd resistance to syngeneic tumor challenge. MC treatment ad no effect on the ability of C3H- mice to reject H-2-comatible skin allografts and H-2 incompatible tumor allografts. 1C also had no consistent effect on the induction of delayed ypersensitivity to dinitrochlorobenzene, as measured by ootpad challenge in BALB/c mice. Based on tumor growth, ate of tumor regression, and, in many cases, final tumor ncidence, four different syngeneic tumors showed some evilence of preferential growth in MC-treated as opposed to ehicle (trioctanoin)-treated mice. The preferential growth of hese tumors in MC-treated mice was not associated with the resence of primary tumors in the test animals. The results ndicate that the immune response to exogenous antigens loes not always correlate with the ability of the host to deal vith syngeneic tumors. They further suggest that there may e a surveillance system against chemically and physically nduced tumors that is distinct from the immune responses o exogenous antigens. (17 refs)

8-3733 **Enhancement of Carcinogenesis by Prostaglandins in Male Albino Swiss Mice.** (Eng) Lupules- u, A. (323 Medical Res. Building, 550 E. Canfield Ave., etroit, MI, 48201). *J Natl Cancer Inst* 61(1): 97-106; 1978.

he effect of prostaglandins E_2 (PGE_2) and $F_2\alpha$ ($PGF_2\alpha$) on he development of 3-methylcholanthrene (3-MC)-induced kin tumors was studied in male albino Swiss mice. Mice were reated topically with 2 ml of a 0.4% acetone soln of 3-MC x/wk for 2 mo and/or 10 -5m-1g PGE_2 $PGF_2\alpha$ every other ay during the same 2 mo. Multiple and large squamous cell arcinomas occurred in 90% of the 3-MC + PGE_2- or PGF α-treated mice at the site of 3-MC treatment. No tumors vere observed in mice treated with 3-MC or PG only. Radi- isotope studies showed a marked increase (15-to 20-fold) in he incorporation of ^{3}H-thymidine, followed by ^{3}H-uridine, H-proline, and ^{3}H-leucine, in the neoplastic cells of mice reated with 3-MC + PG compared with the incorporation een in mice treated with 3-MC alone, PG alone, or in control nice. Electron microscopy showed the predominance of neo- lastic squamous cells with large nuclei, an increased nu- lear:cytoplasmic ratio, dark and light cells with distinct ultrastructural features, increased polysome and dense granule populations, altered mitochondria, and discontinuities of the basement membrane in mice treated with 3-MC and $PGF_2\alpha$/ or PGE_2. Only hyperplastic and dysplastic cellular changes were seen in the epidermis of 3-MC treated mice. The results indicate that $PGF_2\alpha$ and PGE_2 markedly stimulate DNA, RNA, and protein synthesis in hyperplastic epidermal cells following 3-MC application, which may explain their enhancement of cutaneous carcinogenesis. (14 refs)

78-3734 **Lack of Initiating Activity in Mutagens Which Are Not Carcinogenic.** (Eng) Coombs, M. M. (Dept. Chemistry, Imperial Cancer Res. Fund, Lincoln's Inn Fields, London WC2A 3PX, England); Bhatt, T. S. *Br J Cancer* 38(1): 148-150; 1978.

Two noncarcinogenic but mutagenic compounds, 15,16-dihydrocyclopenta[a]phenanthren-17-one (I) and 1,2,3,4-tetrahydrochrysen-1-one (IV), two carcinogenic and mutagenic compounds, 15,16-dihydro-11-methylcyclopenta[a]phenanthren-17-one (III) and 1,2,3,4-tetrahydro-11-methylchrysen-1-one (V), and a noncarcinogen-nonmutagen 15,16-dihydro-3-methylcyclopenta[a]phenanthren-17-one (II), were examined for tumor production in mice using croton oil as a promoting agent. All compounds were applied in four equal doses of 100 μg in 40 μl of toluene on 4 consecutive days to the shaved back of albino TO mice. Starting 1 wk after the last application, 20 animals receiving each compound were promoted twice weekly with 10 μl of a 1% volume/volume soln of croton oil in toluene until the end of the experiment. Twenty mice receiving each compound were treated with the toluene vehicle only. Controls were treated with toluene, croton oil, or III only. Neither crotol oil nor toluene by themselves were carcinogenic. Only the known carcinogens (III) and (V) produced skin tumors; promotion increased the tumor incidence and decreased the latent period. All tumors in mice receiving III alone were carcinomas, but those in animals receiving III or V plus croton oil or toluene were both carcinomas and papillomas. Compounds I and IV are capable of metabolic activation to active species that bind to DNA in vitro and cause mutations in bacteria, but in animal cells, some factors must operate to prevent these active metabolites from damaging the genetic material. (7 refs)

78-3735 **Non-phorbol Mouse Skin Tumor Promoters Do Not Mimic Phorbol Myristate Acetate in Its Effects on Chick Embryo Fibroblasts.** (Eng) Driedger, P. E. (Dept. Pharmacology, Harvard Medical Sch., 250 Longwood Ave., Boston, MA, 02115); Blumberg, P. M. *Int J Cancer* 22(1): 63-69; 1978.

Several compounds that promote mouse skin tumors but are chemically unrelated to the phorbol esters were tested for their abilities to cause loss of large external transformation-sensitive (LETS) protein from chick embryo fibroblasts

(CEF) and to stimulate deoxyglucose (DG) transport in the CEF. After 3 days' exposure of the CEF to max nontoxic levels of the seven test agents, only oleic acid (140 μM) decreased LETS protein > 20% (actual value, 50%), as measured by lactoperoxidase-catalyzed surface radioiodiniation. In contrast, phenol (1 mM) increased LETS protein levels 70%. Only anthralin, lauric acid, and limonene increased DG transport. Iodoacetic acid and cantharidin were inactive in both assays. None of the compounds affected CEF LETS levels or DG transport to the extent that the phorbol esters do. Palmitic and stearic acids, which are structurally similar to oleic acid but do not promote mouse skin tumors, were also inactive in both assays. It is suggested that the phorbol ester promoters and the non-phorbol promoters may have different mechanisms of action. (30 refs)

78-3736 **Cocarcinogens of the Diterpene Ester Type from *Croton flavens* L. and Esophageal Cancer in Curacao.** (Eng) Weber, J. (Deutsches Krebsforschungszentrum, Institut fur Biochemie, Im Neuenheimer Feld 280, D-6900 Heidelberg, W. Germany); Hecker, E. *Experientia* 34(6): 679-682; 1978.

Croton flavens L., a plant widely used in Curacao for a variety of purposes (it is chewed, used to make tea, used topically to relieve oral inflammation, etc), was investigated for possible irritants and cocarcinogens. Three highly irritant and tumor-promoting Croton factors (F_1-F_3) and corresponding three cryptic Croton factors (F_1'-F_3') were isolated from the roots of the plant and characterized as novel esters of 16-hydroxy- and 4-deoxy-16-hydroxyphorbol, respectively. The results suggest that tumor promoters of the phorbol ester type, ingested through the widespread and frequent use of *C. flavens*, may be causally related to the well known high rate of esophageal cancer on Curacao. (21 refs)

78-3737 **Tumor Promoters Inhibit Morphological Differentiation in Cultured Mouse Neuroblastoma Cells.** (Eng) Ishii, D. N. (Dept. Pharmacology, Coll. Physicians and Surgeons Columbia Univ., New York, NY, 10032); Fibach, E.; Yamasaki, H.; Weinstein, I. B. *Science* 200(4341): 556-559; 1978.

The effects of 12-O-tetradecanoyl-phorbol-13-acetate (TPA) and other tumor promotors on the morphologic differentiation of murine neuroblastoma cultures were determined. Cells cultured in the presence of 1.7 x 10^{-7} M TPA [100 nanograms (ng)/ml] during serum deprivation had a 64% inhibition of neurite fiber outgrowth. With a concentration of 5 x 10^{-7} M, the response was inhibited by 75%. TPA (100 ng/1 ml) also blocked neurite outgrowth induced by prostaglandin E_1, papaverine, 5-bromo-2′-deoxyuridine, and hemin. Other macrocyclic plant diterpene tumor promotors, such as phorbol-12,13-didecanoate (PDD) and ingenol dibenzoate, were also effective inhibitors of neurite formation; mezerein, a less potent promotor than TPA, was also a fairly activ neurite inhibitor. Other diterpenes such as phorbol and 4-α PDD, which are not active as skin tumor promotors, hac no effect on neurite formation. The inhibition of neurite outgrowth by TPA was reversible, as indicated by an increas in outgrowth after a 2-hr incubation in the absence of serum (34 refs)

78-3738 **Effects of Retinoic Acid and Juvenile Hormon on the Induction of Ornithine Decarboxylas Activity by 12-O-Tetradecanoylphorbol-13-acetate.** (Eng Kensler, T. W. (McArdle Lab. Cancer Res., Univ. Wisconsin, Madison, WI, 53706); Verma, A. K.; Boutwell, R. K. Mueller, G. C. *Cancer Res* 38(9): 2896-2899; 1978.

When 10 mM 12-O-tetradecanoylphorbol-13-acetate (TPA was added to phytohemagglutinin-treated bovine lymphocyt cultures, ornithine decarboxylase activity was increased 1 times over that in cultures treated with the lectin alone. Thi synergistic action of TPA could be antagonized by simultaneous addition of the acyclic sesquiterpene, insect juvenile hormone III. Retinoic acid (vitamin A acid), an inhibitor of th tumor-promoting action of TPA in mice, was also an effectiv antagonist but required administration to lectin-activatec lymphocytes 1 hr prior to TPA. These data suggest that metabolic activation of retinoic acid is required in order for th compound to exert its antagonistic action. Comparison of th response in the lymphocytes and mouse skin suggests that th lymphocytes provide an excellent system for studying th molecular processes through which phorbol esters and retinoids influence the growth and differentiation of both norma and premalignant cells. (22 refs)

78-3739 **Rapid Stimulation of Phospholipid Metabolisn in Bovine Lymphocytes by Tumor-promoting Phorbol Esters.** (Eng) Wertz, P. W. (McArdle Lab. Cance Res., Univ. Wisconsin, Madison, WI, 53706); Mueller, G. C *Cancer Res* 38(9): 2900-2904; 1978.

The effects of 12-O-tetradecanoylphorbol-13-acetate (TPA), a highly active tumor-promoting agent and lymphocyt comitogen, on phospholipid (PL) metabolism in bovine lymphocytes were studied. TPA accelerated the incorporation o [methyl-^{3}H]choline chloride ([^{3}H-Me]choline) into the PL's of the lymphocytes. Chromatographic analysis of the PL's from lymphocytes exposed to 10^{-8} M TPA for various intervals in the presence of [^{3}H-Me]choline showed that there was a lag period of about 20 min, after which the rate of labeling of phosphatidylcholine, lysophosphatidylcholine, and sphingomyelin were all enhanced. Structure-activity studie showed thathe ability of phorbol diesters to accelerate [^{3}H-Me]choline incorporation was correlated with their potency as lymphocyte comitogens and as tumor promoters. The response to TPA was insensitive to the inhibition o

RNA and protein synthesis by actinomycin D and cycloheximide, respectively, and to the inhibition of membrane movement by cytochalasin B. Retinoic acid, an antagonist of the tumor-promoting and comitogenic actions of TPA, also blocked the acceleration of [^{3}H-Me]choline incorporation into PL's by TPA. The bovine lymphocyte system may be useful for studies of the molecular mechanisms of action of tumor-promoting phorbol esters and their retinoid antagonists. (18 refs)

78-3740 **Stimulation of Prostaglandin Synthesis by Tumor-promoting Phorbol-12,13-diesters in Canine Kidney (MDCK) Cells. Cycloheximide Inhibits the Stimulated Prostaglandin Synthesis, Deacylation of Lipids, and Morphological Changes.** (Eng) Ohuchi, K. (Dept. Biochemistry, Faculty Pharmaceutical Sciences, Tohoku Univ., Sendai, Japan); Levine, L. *J Biol Chem* 253(13): 4783-4790; 1978.

Normal dog kidney cells (MDCK cells: 2×10^5 cells/dish) were incubated with 12-O-tetradecanolyphorbol-13-acetate [TPA: 0.1-10 nanograms (ng)/ml] phorbol-12,13-didecanoate (PDD: 1 ng/ml), or 4α-phorbol-12,13-didecanoate (4α-PDD: 100 ng/ml) for 60 min in 4 ml of non-serum-supplemented medium. The cells were then washed with minimal essential medium and incubated with 4 ml of serum-supplemented medium for various periods of time. TPA and PDD, but not 4α-PDD, stimulated the deacylation of cellular lipids, prostaglandin (PG) biosynthesis, and morphological changes in the MDCK cells. The levels of PGE2 and PGF2 increased with time of incubation. Stimulation of PG production was a slow process, and at low concentrations of promoters the reaction(s) was not complete even after 24 hr. There was a pronounced lag time, the length of which depended on promoter concentration. Cells treated with TPA and PDD had long, thin processes and they appeared longer and thinner than normal cells. They seemed to have much less contact with neighboring cells, and giant cells with multiple processes were seen occasionally. These morphological changes also required at least 24 hr for expression. Cycloheximide (0.005-1.0 μg/ml) inhibited the stimulated PG biosynthesis, the changes in morphology, and the increased lipid deacylation, but hydrocortisone (1.0 μg/ml) did not. Indomethacin (0.5 μg/ml) inhibited the PG biosynthesis completely and some of the lipid deacylation, but it did not affect the morphological changes. (31 refs)

78-3741 **Inflammatory, Tumor Initiating and Promoting Activities of Polycyclic Aromatic Hydrocarbons and Diterpene Esters in Mouse Skin as Compared with Their Prostaglandin Releasing Potency In Vitro.** (Eng) Brune, K. (Dept. Pharmacology, Biozentrum der Universitat, CH-4056 Basel, Switzerland); Kalin, H.; Schmidt, R.; Hecker, E. *Cancer Lett* 4(6): 333-342; 1978.

Release of prostaglandin E_2 (PGE_2) from cultured peritoneal macrophages of NMRI mice by skin irritant tumor initiators and promoters was investigated. 7,12-Dimethylbenz(a)anthracene (DMBA) caused slight irritation on the mouse ear, but even relatively high doses (10^{-6})did not stimulate PGE_2 release to any measurable extent within 4 hr after administration. Apparently, there is no correlation between the irritating and initiating activity in mouse skin and PGE_2 release from macrophages. On the other hand, promoters of the diterpene ester type, eg, 12-O-tetradecanoylphorbol-13-acetate (TPA), were strong irritants on the mouse ear and, even at low doses (10^{-7} and 10^{-8} M), they stimulated PGE_2 release from macrophages dramatically within 1 hr after administration. Moreover, a good correlation was established between irritating and promoting activity in mouse skin and PGE_2 release from macrophages for a series of tigliane-, ingenane- and daphnane-type diterpene derivatives. The results suggest that the rapid and specific release of PGE_2 from macrophages by the diterpene esters may also take place in the epidermal cells of the target tissue. This event could initiate both skin irritation and cell proliferation. (21 refs)

78-3742 **Effects of Multiple Phorbol Myristate Acetate Treatments on Cyclic Nucleotide Levels in Mouse Epidermis.** (Eng) Garte, S. J. (Inst. Environmental Medicine, New York Univ. Medical Center, New York, NY, 10016); Belman, S. *Biochem Biophys Res Commun* 84(2): 489-494; 1978.

The effects of repeated applications of phorbol myristate acetate (PMA) on cyclic nucleotide levels and ratios in mouse epidermis were studied with the use of 6- to 8-wk old female Swiss Ha/ICR mice. A tumor-initiating dose of 25 μg 7,12-dimethylbenz(a)anthracene was applied to the shaved skin of the back of each mouse. One week later, the first dose of 10 μg PMA was applied. PMA treatments were repeated 3x/wk, and animals received 1, 2, 10, or 20 applications. Animals were sacrificed 2, 36, 72, or 120 hr after the last PMA application. Filtered homogenates of epidermis or tumors from the treated skin area were assayed for cyclic AMP (cAMP), cyclic 3′,5′-guanosine monophosphate (cGMP), and DNA. There were slight but significant ($p < 0.05$) decreases in cAMP and dramatic (5- to 10-fold) increases in cGMP after multiple PMA treatments. Increases were greater at 120 hr after the last treatment than at 2 hr. After two more treatments, the cyclic nucleotide levels and the ratios of AMP and GMP to DNA in the isolated solid tumors were very close to those found in the epidermis. (15 refs)

78-3743 **Effects of 7,8-Benzoflavone on Skin Tumor-initiating Activities of Various 7- and 12-Substituted Derivatives of 7,12-Dimethylbenz(a)anthracene in Mice.** (Eng) DiGiovanni, J. (Dept. Pharmacology, Univ. Washington Sch. Medicine, Seattle, WA, 98105);

Slaga, T. J.; Viaje, A.; Berry, D. L.; Harvey, R. G.; Juchau, M. R. *J Natl Cancer Inst* 61(1): 135-140; 1978.

The skin tumor-initiating activities of various 7- and 12-substituted derivatives of 7,12-dimethylbenz(a)anthracene (DMBA) were investigated in female outbred Charles River CD-1 mice. 7-Formyl-12-methylbenz(a)anthracene (7-CHO-12-MBA), at a dose 74-fold greater than that of DMBA [740 nanomoles (nmol)/mouse], was as effective tumor initiator. 7,8-Benzoflavone (7,8-BF) inhibited the tumor-initiating activity of 7-CHO-12-MBA by 51%. 12-Formyl -7- methylbenz(a)anthracene and 7,12-diformylbenz(a)anthracene, applied at initiating doses of 740 and 704 nmol/mouse, respectively, were much less active than 7-CHO-12-MBA. 7-Bromomethyl-12-methylbenz(a)anthracene (7-BRME-12-MBA) was a more effective tumor initiator than 7-bromomethylbenz(a)anthracene (7-BRMEBA), but both were less active than DMBA. 7,8-BF inhibited the tumor-initiating activity of 7-BRME-12-MBA and 7-BRMEBA by 34% and 54%, respectively. 12-Bromomethyl-7-methylbenz(a)anthracene (12-BRME-7-MBA) was as active an initiator as 7-BRME-12-MBA. 7,8-BF inhibited tumor initiation with 12-BRME-7-MBA by 29%. Three naturally occurring flavones and the cytochrome P_{450} inhibitor 1-benzylimidazole were investigated after topical application (100 μg) for their effects on tumor initiation with DMBA. Quercetin inhibited tumor initiation with DMBA by 22%, but myricetin and 4′,5,7-trihydroxyflavonone enhanced tumor initiation by 54% and 29%, respectively. 1-Benzylimidazole had no effect. The abilities of the flavones and 1-benzylimidazole to inhibit aryl hydrocarbon hydroxylase (AHH) in vitro did not correlate with their effects on tumor initiation with DMBA. This suggests that AHH is not the only enzyme system involved in DMBA tumorigenesis and that 7,8-BF may produce inhibition by affecting some other system. (39 refs)

78-3744 **Quantitative Histological Changes During Early Experimental Carcinogenesis in the Hamster Cheek Pouch.** (Eng) Eveson, J. W. (Dept. Oral Medicine and Pathology, Glasgow Dental Hosp., Glasgow, Scotland); MacDonald, D. G. *Br J Dermatol* 98(6): 639-644; 1978.

Fifteen male Syrian golden hamsters had their cheek pouches painted with 9,10-dimethyl-1,2-benzanthracene (DMBA: 0.25% soln in acetone) 3x/wk for a max of 6 wk. Groups of five animals were sacrificed after 3 wk of painting, 6 wk of painting, and 3 wk after the last application. Early sequential changes in the cheek pouch epithelium were quantified. At 3 wk, the epithelium was in the inflammatory phase and was twice the normal thickness, the stratum corneum was three times the normal thickness. The increased size of the cellular compartments was due to increases in the size of the individual progenitor (P) and maturation (M) cells, their numbers actually being reduced. At 6 wk, the epithelium and stratum corneum were thicker, but the inflammatory reaction was less severe. The increased thickness of the cellular compartments was due to a recovery in the number of M cells and an increase in the number and size of the P cells. At 9 wk, overall epithelial thickness was the same, but the size of the keratinized compartment decreased and that of the cellular compartments increased. This suggests that much of the early increase in stratum corneum thickness was due to hyperplastic rather than neoplastic action of the carcinogen. The increased thickness of the cellular layers appeared due to a progressive increase in the size and number of P cells; ie, P cell hyperplasia and hypertrophy. (13 refs)

78-3745 **Protection Against 7,12-Dimethylbenz(a)anthracene-induced Rat Mammary Carcinoma by Infection with Mouse Xenotropic Type C Virus.** (Eng) Weislow, O. S. (Viral Oncology Program, NCI Frederick Cancer Res. Center, Box B, Frederick, MD, 21501); Allen, P. T.; Shepherd, R. E.; Twardzik, D. R.; Fowler, A. K.; Hellman, A. *J Natl Cancer Inst* 61(1): 123-129; 1978.

The possibility that preinfection with a live xenotropic virus may reduce the incidence of chemically induced neoplastic disease was investigated. Female outbred Sprague-Dawley rats were inoculated ip with a viable mouse xenotropic C-type virus, M55 (2 x 10^6 focus-inducing units), 7 days prior to po administration of 7,12-dimethylbenz(a)anthracene (DMBA; 0.1 mg/g). Another group of rats was administered DMBA only. The incidence of tumor formation was 90% in the DMBA-treated rats at day 140. In contrast, tumor incidence in the M55 virus-infected and DMBA-treated group only rose to 35% by day 133 and did not exceed this level. M55 virus inoculation also delayed the onset of tumor formation by 3 wk. Infectious virus could not be isolated from organs of the infected rats, but high titers of circulating and tumor-associated antibodies were detected against the viral internal core protein p30, and a low-grade antibody response to intact virus or envelope glycoprotein was found. A cell-mediated immune response, measured by lymphocyte transformation, was detected with intact virus but not with p30 antigen. No immunity developed after a single inoculation of UV-inactivated virus. It is concluded that infection of a heterologous species with a live, nonpathogenic xenotropic mouse virus protects against DMBA-induced mammary carcinoma. The mechanism of this protection is not known. (62 refs)

78-3746 **Chromosome Changes (Trisomy 15) in Murine T-Cell Leukemia Induced by 7,12-Dimethylbenz(a)anthracene (DMBA).** (Eng) Wiener, F. (Dept. Tumor Biology, Karolinska Institutet, S-104 01 Stockholm 60, Sweden); Spira, J.; Ohno, S.; Haran-Ghera, N.; Klein, G. *Int J Cancer* 22(4): 447-453; 1978.

A series of T-cell leukemias induced in female C57BL/6 mice by 7,12-dimethylbenz(a)anthracene (DMBA: 1 mg/wk x 4, via stomach tube) was studied cytogenetically. After leuemia development, tumor cells were inoculated either iv or p in syngeneic males. Tumors subjected to chromosome anding analysis were from the first, second, or third transplantation generations. The modal number of the leukemia ells fell into three categories: a 41 stemline, a 43 stemline nd a 36 and 37 + 2 two-armed chromosome stemline. All nalyzed leukemia cells had a trisomy of chromosome 15. umor cells with a modal number of 43 displayed additional risomies of chromosomes 19 and 14. These findings suggest hat chromosome 15 trisomy is the first detectable specific hromosome change associated with the development of DMBA-induced T-cell lymphomas. A similar association was previously shown with regard to the development of adiation leukemia virus-induced T-cell lymphomas. These findings support the idea that in tumors of diverse etiologies, ommon cytogenetic changes may appear in the same common target-cell precursor by a convergent microevolution-type process. 78-3747 **Binding of 7,12-Dimethylbenz(a)anthracene to BALB/c Mouse Mammary Gland DNA in Organ Culture.** (Eng) Kundu, A. B. (Tumor Biology Lab., School Life Sciences, Univ. Nebraska, 201 Lyman Hall, Lincoln, NB, 68588); Telang, N. T.; Banerjee, M. R. *J Natl Cancer Inst* 61(2): 465-469; 1978.

Binding of 7,12-dimethylbenz(a)anthracene (DMBA) to BALB/c mouse mammary gland DNA in organ culture was studied, and the ability of DMBA and several other hydrocarbons to induce nodulelike alveolar lesions (NLAL) in the mammary glands in culture was assessed. The second thoracic mammary glands of immature female BALB/c mice were cultivated to alveolar development in a chemically defined medium containing insulin, prolactin, aldosterone, and hydrocortisone (IPAH medium). The glands were treated with labeled (^{3}H or ^{14}C) or unlabeled DMBA for 24 hr between days 3 and 4 of culture. The DNA of glands treated with labeled DMBA contained bound radioactivity. Nearly 100% of the initial radioactivity was retained up to 5 mo, 72% up to 8 mo. Morphological studies after treatment of the glands with equimolar concentrations (0.004 M) of DMBA, dibenz(a,h)anthracene (DBA), benz(a)anthracene (BA), or anthracene in IPAH medium indicated that DMBA was the most potent in inducing NLAL. The incidence of NLAL induced by DBA was about half that induced by DMBA. The NLAL-inducing capacity of BA was even lower, and anthracene showed little effect. Thus, the binding of DMBA to DNA corresponds to its high noduligenic action in the mammary glands in this organ culture model. Similar biochemical interactions between DMBA and cellular DNA are believed to be characteristic of DMBA oncogenesis in other cell types. (31 refs)

78-3748 **Biological Evaluation of Euphorbia Latices in Iran: I. Tumour Producing Effect in Mice.** (Eng) Zarrin, K. (Taj Pahlavi Cancer Inst., Pahlavi Medical Sch., Tehran, Iran); Aynehchi, Y. *Tumor Res (Sapporo)* 12: 47-51; 1977.

The tumor-initiating and -promoting activity of latex derived from eight species of *Euphorbia* was investigated in Iran KZ albino mice. The species included *E. bungi* Boiss., *E. lanta* Sieb., *E. tinctoria* Boiss., *E. virgata* L., *E. microsciadia* Boiss. et Buhse., *E. esula* L., *E. gerardiana* Jacq., and *E. larica* Boiss. In the first experiment, a 10% extract of *Euphorbia* latex in 0.5 ml acetone was applied to the shaved back once weekly for 26 wk. Tumors were noted in mice treated with extracts of *E. tinctoria, E. virgata, E. microsciadia,* and *E. gerardiana.* Papillomas were noted by week 10, and by week 26, 22/76 survivors had papillomas. Ulceration and crusting of the skin were observed in eight animals. All skin lesions eventually healed; no malignant tumors were noted by 40 wk. In a second experiment, mice were treated with either a single dose of 300 μg 9,10-dimethyl-1,2-benzanthracene (DMBA) to the shaved dorsal skin or DMBA plus an *Euphorbia* extract on day 1 and weekly applications of the extract beginning 3 wk later. By 26 wk, 1/79 surviving animals treated with DMBA only had papillomas compared with 60/74 in those treated with DMBA + extract. Papillomas were first noted in the latter group during week 8 of promotion. No malignant tumors were noted by 40 wk. It was concluded that extracts of *Euphorbia* contain a potent tumor-promoting substance. (8 refs)

78-3749 **Effects of Reserpine on the Incidence of 9,10-Dimethyl-1,2-benzanthracene-induced Tumors in Pinealectomised and Thymectomised Rats.** (Eng) Lapin, V. (Inst. Cancer Res., Univ. Vienna, 1090 Vienna IX, Austria). *Oncology* 35(3): 132-135; 1978.

The effects of reserpine administration on the incidence of 9,10-dimethyl-1,2-benzanthracene (DMBA)-induced tumors was investigated in Wistar rats, that had been pinealectomized (PiX) and/or thymectomized (Tx) neonatally. At 3-3.5 mo of age, the rats were given three doses of DMBA (50 mg po) 10 days apart and, 1 mo after the first DMBA dose, some of the rats were also given reserpine (100 μg/kg sc) daily for 40 consecutive days. Another group of rats received reserpine only. In the rats that received DMBA only, there was a 50% tumor occurrence in all animals, with or without surgery. Administration of DMBA + reserpine led to a slight increase in tumor incidence in normal and Tx rats; however, in Pix and Tx-Pix rats, tumor incidence was 100%. None of the animals that received reserpine only suffered any harmful effects. Tumor occurring most frequently were mammary gland and ear duct tumors, both of which are hormone-dependent. Leukemia appeared at a very high rate in Tx-Pix rats after DMBA + reserpine treatment. Mean survival time in these rats was 168.5 days. It is suggested that neuroendocrine alterations in pituitary prolactin secretion due to the neonatal removal of the pineal gland, remain latent and become evident after reserpine administration as reflected in increased tumor incidence. 78-3750 Gangliosides and Their Cell Density-Dependent Changes in Control and Chemically Transformed C3H/10T1/2 Cells. (Eng) Langenbach, R. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, Omaha, NE, 68105); Kennedy, S. *Exp Cell Res* 112(2): 361-372; 1978.

The effect of in vitro chemical transformation on the cellular gangliosides (GS) of C3H/10T1/2 mouse embryo cells was determined, and the possible involvement of GS biosynthesis mechanisms in the density-dependent regulation of cell growth was investigated. The transformants were progeny of line C3H/10T1/2, cloned after treatment with 7,12-dimethylbenz(a)anthracene (DMBA-TCL1 cells) or 3-methylcholanthrene (MCA-TCL15 cells). All three cell types contained a complex pattern of GS, but the transformants had increased levels of the simplest GS (GM_3) and reduced levels of more complex GS. In the C3H/10T1/2 cells, however, as cell-to-cell contact increased, incorporation of ^{14}C-glucosamine into GS showed that GM_3 synthesis was decreased and synthesis of a more complex GS (GD-1a) was increased. In the transformants, the percentage of each individual GS (with respect to total labeled GS) was only slightly altered with changing cell density. As cell density increased, turnover of ^{14}C-glucosamine-labeled GS was approx equal in C3H/10T1/2 cells and MCA-TCL15 cells but more rapid in DMBA-TCL1 cells. Most individual GS turned over at about the same rate except for GD-1a, which increased slightly (relative to percentage of total labeled GS) in all three cell types. Labeling data indicated that the majority of most GD-1a synthesis was de novo. When exogenous complex GS were added to the medium of C3H/10T1/2 and DMBA-TCL1 cells, they inhibited cellular DNA synthesis and caused both lines to incorporate an increased percentage of ^{14}C-glucosamine into GS more complex than GM_3. These and similar findings raise interesting questions about the use of glycolipids for phenotypic reversion of transformed cells, as potential chemotherapeutic agents, and for the immunological detection of transformed cells. 78-3751 Particle-enhanced Membrane Uptake of a Polynuclear Aromatic Hydrocarbon: A Possible Role in Cocarcinogenesis. (Eng) Lakowicz, J. R. (Freshwater Biological Inst., Univ. Minnesota, P.O. Box 100, Navatte, MN, 55392); Englund, F.; Hidmark, A. *J Natl Cancer Inst* 61(4): 1155-1159; 1978.

The effect of a particulate, silica, on the rate of membrane uptake of benz(a)anthracene (BA) was studied. The fluorescence emission spectrum and quantum yield of BA, when adsorbed to silica, underwent spectral shifts upon addition of phospholipid vesicles. These spectral changes appeared to result from the transfer of BA from the silica surface into the lipid bilayer. These spectral changes were used to measure the rates of membrane uptake of BA from the silica-adsorbed state and from the crystalline and microcrystalline states of BA. Adsorption of BA to silica resulted in an increased rate of uptake of BA into dipalmitoyl-L-α-phosphatidylcholine vesicles compared with the uptake rate into these vesicles from crystalline states. This particle-enhanced membrane uptake of chemical carcinogens may be of importance in explaining the enhanced carcinogenicity of polynuclear aromatic hydrocarbons in the presence of particulate matter. 78-3752 Emission of Polycyclic Aromatic Hydrocarbons in the Electrochemical Industry. Accumulation and Effect of Polycyclic Aromatic Hydrocarbons on the Marine Environment. (Fin) Knutzen, J. (NIVA, Finland). *Kjemi* 38(1): 42-43; 1978.

The accumulation and effect on the marine environment of polycyclic aromatic hydrocarbons (PAH) contained in effluents generated in the electrochemical industry are reviewed. PAH have been found in the effluents in concentrations of 0.1-1 ppm. Two PAH, benzanthrone and creosote, caused tumors in red algae and seaweed. (no refs)

78-3753 7,12-Dimethylbenz(a)anthracene-DNA Products in Mammalian Cells and Salmonella Strains (Meeting Abstract). (Eng) Bigger, C. H. (Chemical Carcinogenesis, NCI Frederick Cancer Res. Center, Frederick, MD, 21501); Andrews, A. W.; Moschel, R. C.; Dipple, A. *Mutat Res* 53(2): 152; 1978. (no refs)

78-3754 Microsome-mediated Mutagenicities of the Dihydrodiols of 7,12-Dimethylbenz(a)anthracene: High Mutagenic Activity of the 3,4-Dihydrodiol. (Eng) Malaveille, C. (Unit Chemical Carcinogenesis, International Agency Research Cancer, 150 cours Albert Thomas, 69372 Lyon, France); Bartsch, H.; Tierney, B.; Grover, P. L.; Sims, P. *Biochem Biophys Res Commun* 83(4): 1468-1473; 1978.

7,12-Dimethylbenz(a)anthracene (DMBA) and its 3,4-, 5,6-, 8,9-, and 10,11-dihydrodiols were tested for mutagenicity toward *Salmonella typhimurium* TA100 in the presence of rat liver post-mitochondrial supernatants from Aroclor-treated rats. At substrate concentrations of 5 μM, the non-K-region 3,4-dihydrodiol was the most active of all the compounds tested, being six times more mutagenic than the parent hydrocarbon. At higher concentrations, its mutagenic activity decreased because of cytotoxicity. The other two non-K-region dihydrodiols, the 8,9- and 10,11-dihydrodiols, were less mutagenic than the parent hydrocarbon. The K-region 5,6-dihydrodiol showed weak mutagenic activity at nontoxic concentrations. These results suggest that, of the dihydrodiols tested, the 3,4-dihydrodiol is the one most likely to be involved in the metabolic activation of DMBA. Since this dihydrodiol requires further metabolic activation, one or both of the isomeric forms of the 3,4-dihydrodiol-1,2-epoxide might be involved. (20 refs)

78-3757 **Cellular Uptake, Transport, and Macromolecular Binding of Benzo(a)pyrene and 7,12-Dimethylbenz(a)anthracene by Human Cells In Vitro.** (Eng) Ekelman, K. B. (Dept. Physiological Chemistry, Ohio State Univ., Columbus, OH, 43210); Milo, G. E. *Cancer Res* 38(9): 3026-3032; 1978.

Evidence of the uptake, cytoplasmic protein binding, and nuclear translocation of benzo(a)pyrene (BP) and 7,12-dimethylbenz(a)anthracene (DMBA) by monolayer cultures of preconfluent human neonatal foreskin (HNF) fibroblasts is reported. The max concentration of DMBA in the whole-cell fraction was 6% of the max BP concentration in that fraction, and the max DMBA concentration in the nuclear fraction was 2% that of max nuclear-associated BP. Approx 30% of BP present in the cytoplasm of human fibroblasts was bound DMBA. In BP-treated cells, the extent of polynuclear hydrocarbon uptake by the bound cytoplasmic and nuclear fractions was approx the same; BP appeared first in the bound cytoplasmic fraction and then in the nuclear fraction. The binding of BP to cytoplasmic protein and translocation of this bound polynuclear hydrocarbon to the nucleus appeared to be a function of one or several metabolites of the parent hydrocarbon. In DMBA-treated cells, the pattern and extent of uptake by the crude cytoplasmic fraction were approx the same as those of the nuclear fraction, indicating random dispersal of DMBA throughout the cell. Microelectrophoresis of a cell extract prepared from ^{3}H-BP-treated HNF cells suggested that the ^{3}H-BP-cytoplasmic protein association was noncovalent. (41 refs)

78-3758 **Increased Sensitivity for Detection of Carcinogen-induced DNA Repair with the Chain Terminator Dideoxythymidine.** (Eng) Smith, G. J. (Dept. Pathology, Univ. North Carolina Sch. Medicine, Chapel Hill, NC, 27514); Charlton, R. K.; Grisham, J. W.; Kaufman, D. G. *Biochem Biophys Res Commun* 83(4): 1538-1544; 1978.

DNA excision repair was evaluated in cultured primary hepatocytes following benzo(a)pyrene (BP: 5 or 25 μM) treatment with and without the chain terminators 2′,3′-dideoxythymidine (ddThd: 10 μg/ml) and trifluorothymidine (F_3Thd: 5 μg/ml) in the incubation medium. After 18 hr of incubation, the cells were subjected to alkaline sucrose gradient centrifugation. Eighty-three percent of the DNA from control cells sedimented into the bottom fractions of the gradient, compared with 22% of the DNA from cells exposed to 25 μM BP and incubated with ddThd and F_3Thd. DNA from cells exposed to 25 μM BP alone gave a sedimentation pattern similar to that of control cells, with 68% of the DNA reaching the bottom half of the gradient. Therefore, the inhibitors greatly increased the proportion of slowly sedimenting DNA. For cells exposed to 5 μM BP in the presence of ddThd and F_3Thd, 48% of the total DNA was found in the upper half of the gradient. Under similar conditions, 60% of the DNA from cells exposed to 25 μM BP plus the inhibitors was found in these fractions. Thus, the reduction in DNA sedimentation velocity produced by ddThd and F_3Thd exposure is related to carcinogen dose. DNA chain discontinuities caused by chain growth termination at sites of repair are, collectively, the major contributor to the reduced DNA sedimentation rate, the characteristic observed by this assay, which is more sensitive than those currently available. (14 refs)

78-3759 **Role of Particle Size in the Formation of Respiratory Tract Tumors Induced by Benzo(a)pyrene.** (Eng) Stenback, F. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, 42nd and Dewey Ave., Omaha, NB, 68105); Rowland, J. *Eur J Cancer* 14(4): 321-326; 1978.

The role of particle size in experimental respiratory tumor formation was studied by intratracheal instillation of two different particle sizes of benzo(a)pyrene (BP) into Syrian golden hamsters. The hamsters received 3 mg BP in large particles (64% >10 μm) or small particles (98% <10 μm) once weekly for 18 wk. Respiratory tract tumors were found in 5/48 animals receiving small particles and in 31/48 animals receiving the larger particles. The small particles cleared much more rapidly from the lungs than did the larger particles. These results indicate the important role of particle size in the experimental induction of respiratory tract tumors. (20 refs)

78-3760 **Analysis of Benzo(a)pyrene Metabolism by High-Pressure Liquid Chromatography.** (Eng) Selkirk, J. K. (Cancer and Toxicology Section, Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN). *Adv Chromatogr* 5(16): 1-36; 1978.

The ease with which high-pressure liquid chromatography can obtain reproducible data on the critical biochemical structural information concerning benzo(a)pyrene (BP) metabolism is exemplified. Four BP phenols were established as metabolites, 3-OH-BP and 9-OH-BP and the newly identified 1-OH-BP and 7-OH-BP. Literature on the metabolism of BP is reviewed. (59 refs)

78-3761 **Analysis of Mutagenic Activity of Benzo(a)pyrene.** (Rus) Krasovskii, G. N. (A. N. Sysin Inst. General and Communal Hygiene, Moscow, USSR); Sokolovskii, V. V.; Varshavskaia, S. P. *Gig Sanit* (3): 102-103; 1978.

To test whether minimal carcinogenic doses of benzo(a)pyrene are mutagenic, random-bred mice were treated with a total of 0.001, 0.01, or 0.1 mg BP given in 10 instillations at 2-day intervals. One day after the last injection, the mice were sacrificed and bone marrow specimens were analyzed. The incidence of chromosome aberrations in the three dosage groups (1.34%, 1.54%, and 1.84%, respectively) was similar to that in controls (1.34%). These findings indicate that BP is not mutagenic at these minimal doses. (5 refs)

78-3762 **Formation of Mutagens in Beef and Beef Extract During Cooking.** (Eng) Commoner, B. (Center Biology Natural Systems, Washington Univ., St. Louis, MO, 63130); Vithayathil, A. J.; Dolara, P.; Nair, S.; Madyastha, P.; Cuca, G. C. *Science* 201(4359): 913-916; 1978.

Studies designed to determine the origin of the mutagens detected in bacterial media that contain beef extract are reported. Beef stock was prepared and then boiled (at temperatures not exceeding 105 C) in an open beaker for 10 hr. Samples were taken at intervals and analyzed for mutagenic activity (MA). Methylene chloride extracts of the stock were tested on histidine-negative *Salmonella typhimurium* strain TA1538 in the presence of a microsomal preparation. An initial sample yielded an av of 21 revertants/plate (vs control value of 29), an 8.5-hr sample yielded 181 revertants/plate, and a 10-hr sample (a dark-brown paste similar to commercial beef extract) yielded 1,572 revertants/plate. Since the mutagens in beef extract are produced in conditions that may be encountered in cooking procedures, their occurrence was determined in cooked beef. Lean ground beef was cooked (at temperatures not exceeding 200 C) on an electric hot plate or home hamburger cooker, and samples were taken after 1.5, 3.0, and 5.5 min and analyzed as above for MA. In the absence of a microsomal preparation, the MA's fell within the range of control values, but in the presence of this preparation, all cooked samples yielded substantial MA. The number of revertants increased with cooking time. The mutagens that occurred in the beef extract and cooked beef were compare chromatographically with those formed by pyrolysis o amino acids and protein and with benzo(a)pyrene (BP These analyses indicated that the mutagens that occurred i the beef stock and ground beef (which were indistinguishab from each other) were distinguishable from both BP and th mutagens produced from pyrolyzed amino acids and protein Well-done hamburgers were calculated to contain about 0.1 ppm of the mutagens and beef bouillon cubes that contai beef extract, about 0.1 ppm. Since these mutagens may b potentially carcinogenic and are formed during ordinar cooking procedures, their occurrence raises questions abou possible risks to human health. (10 refs)

78-3763 **Marked Differences in the Carcinogenic Activity of Optically Pure (+)- an (-)-trans-7,8-Dihydroxy-7,8-dihydrobenzo(a)pyrene in Newborn Mice.** (Eng) Kapitulnik, J. (Dept. Pharmacology Hadassah-Hebrew Univ. Medical Sch., Jerusalem, Israel) Wislocki, P. G.; Levin, W.; Yagi, H.; Thakker, D. R.; Akagi H.; Koreeda, M.; Jerina, D. M.; Conney, A. H. *Cancer Re* 38(9): 2661-2665; 1978.

Optically pure (+)- and (-)-trans-7,8-dihydroxy-7,8-dihydrobenzo(a)pyrene [(+)- and (-)-BP 7,8-dihydrodiol] wer tested for carcinogenicity in newborn Swiss-Webster mice The mice were inoculated ip with 20, 40 and 80 nanomole (nmol) of either compound on days 1, 8, and 15 of life, respectively. The animals were killed at 17 wk of age. Control mic had 0.10 pulmonary adenoma per mouse, whereas animal treated with (+)-BP 7,8-dihydrodiol and (-)-BP 7,8-dihydrodiol had 0.16 and 9.28 pulmonary adenomas per mouse respectively. When a fivefold higher dose was administere according to the above dosage schedule, (+)-BP 7,8-dihydrodiol caused 2.34 pulmonary adenomas per mouse an (-)-BP 7,8-dihydrodiol caused 32.2 pulmonary adenomas pe mouse. When 200, 400, and 800 nmol of benzo(a)pyrene (BP or (+)-BP 7,8-dihydrodiol were administered sequentially o days 1, 8, and 15 of life, 4.13 and 18.5 pulmonary adenoma per mouse, respectively, were observed when the mice wer 27 wk of age. This high dose of (-)-BP 7,8-dihydrodiol kille most of the mice. Administration of (-)-BP 7,8-dihydrodi caused a high incidence of malignant lymphomas, wherea (+)-BP 7,8-dihydrodiol and BP had little or no ability t cause malignant lymphomas. (30 refs)

78-3764 **Explant Culture of Human Colon.** (Eng) Autrup, H. (NCI, NIH, Building 37, Room 3A09 Bethesda, MD, 20014); Barrett, L. A.; Jackson, F. E.; Jesudason, M. L.; Stoner, G.; Phelps, P.; Trump, B. F.; Harris, C C. *Gastroenterology* 74(6): 1248-1257; 1978.

Nontumorous colonic tissues from patients with or withou cancer were cultured as explants in a chemically define medium for > 4 to 20 days. The viability of the explants wa shown by the preservation of the ultrastructural features to the colonic epithelial cells and by the active incorporation of radioactive precursors into cellular DNA and protein. A progressive decrease in the number of goblet cells, a decrease in the depth of the crypts, and a change from a columnar to a cuboidal epithelium were observed. After 20 days in culture, the colonic mucosa consisted of a single layer of cuboidal epithelial cells and a few glands. The survival of colonic mucosa in culture was subject to both intra- and interindividual variation. Cultured human colonic mucosa also activated a chemical procarcinogen, benzo(a)pyrene (BP), into metabolites that bound to cellular DNA. BP binding levels in 32 explants (7 from patients with colon cancer) had a unimodal distribution, and the values varied from 0.2 to 20 picomoles/10 mg DNA (median value, 4.5). Possible factors in the one hundredfold interindividual variation in binding levels are discussed. (20 refs)

78-3765 **Carcinogenicity and Metabolic Profiles of 6-Substituted Benzo(a)pyrene Derivatives on Mouse Skin.** (Eng) Cavalieri, E. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, 42nd and Dewey Ave., Omaha, NB, 68105); Roth, R.; Grandjean, C.; Althoff, J.; Patil, K.; Liakus, S.; Marsh, S. *Chem Biol Interact* 22(1): 53-67; 1978.

Benzo(a)pyrene (BP) and nine 6-substituted derivatives were applied to the shaved back skin of 8-wk-old female Swiss mice in order to analyze the relative carcinogenicity of these compounds. The mice were treated with 0.2 micromole (μmol) of compound in acetone 4x/wk for 20 wk. In addition, the metabolism of the compounds was studied using mouse skin homogenates in vitro and mouse skin in vivo. Only four compounds were carcinogenic, and the order of potency was BP > 6-methylbenzo(a)pyrene (BP-6-CH_3), > 6-hydroxymethylbenzo(a)pyrene (BP-6-CH_2OH) = benzo(a)pyrene-6-carboxaldehyde (BP-6-CHO). Because the latter two compounds were partially in suspension, the small difference in their carcinogenicity could not be assessed. This problem was resolved in a further experiment, in which the carcinogenicity of these two compounds plus that of BP-6-CH_3 and 6-hydroxymethylbenzo(a)pyrene sulfate ester (BP-6-CH_2OSO_3Na) was compared at three dose levels (0.8, 0.2, and 0.05 μmol, 2x/wk for 40 wk). BP-6-CH_2OSO_3Na proved to be a more potent carcinogen than BP-6-CH_2OH, which in turn was more active than BP-6-CHO. The greater carcinogenicity of BP-6-CH_3 relative to that of BP-6-CH_2OH and BP-6-CHO was confirmed, suggesting that BP-6-CH_2OH is not a proximate carcinogenic metabolite for BP-6-CH_3. Since BP-6-CHO was weaker than BP-6-CH_2OH and was efficiently reduced metabolically to BP-6-CH_2-OH, the latter may be a common proximal carcinogenic metabolite. The more potent carcinogenicity of BP-6-CH_2OSO_3Na relative to that of BP-6-CH_2OH suggests that an ester of the latter might be the ultimate alkylating compound reacting with cellular nucleophiles. (30 refs)

78-3766 **Increase of Liver Microsomal Benzo(a)pyrene Monooxygenase Activity by Subsequent Glucuronidation.** (Eng) Bock, K. W. (Institut fur Pharmakologie und Toxikologie der Universitat, Kreuzbergring 57, D-3400 Gottingen, W. Germany). *Naunyn Schmiedebergs Arch Pharmacol* 304(1): 77-79; 1978.

Benzo(a)pyrene (BP) monooxygenase activity in rat liver microsomes was measured with and without subsequent addition of uridine diphosphate (UDP)-glucuronic acid (UDPGA) and/or UDP-N-acetylglucosamine (UDPNAG) to the incubation medium. The microsomes were obtained from rats pretreated with 3-methylcholanthrene (3-MC) or phenobarbital. BP monooxygenase activity was significantly increased when the assay was performed in the presence of UDPGA and further increased by the addition of UDPNAG, which is an allosteric activator of UDP-glucuronyltransferase. Specific enzyme activities found with microsomes from untreated, phenobarbital-, or 3-MC-treated rats were 0.5, 0.5 and 1.6 nanomoles/min/mg protein, respectively. However, the increase of monooxygenase activity by the addition of both UDPGA and UDPNAG was similar (180%, 200%, and 219% with microsomes from untreated, phenobarbital-, and 3-MC-treated rats, respectively). Experiments with guinea pig liver microsomes produced similar results. The results suggest that there is a coupling between microsomal monooxygenase and UDP-glucuronyltransferase. This coupling may be involved in the elimination of toxic compounds. (12 refs)

78-3767 **A Comparative Study of Aryl Hydrocarbon Hydroxylase Induction in Rat Liver and Lungs by 5,6-Benzoflavone.** (Fre) Queval, P. (Charge de Recherches a l'INSERM, Laboratoire de Pathologie pleuropulmonaire F.R.A., 16 INSERM, Hopital Laennec, 42, rue de Sevres, 75007 Paris, France); Beaumatin, J. *Rev Fr Mal Respir* 6(2): 191-194; 1978.

Induction of the microsomal enzyme aryl hydrocarbon hydroxylase (AHH) was measured in the livers and lungs of 3- to 4-mo-old Sprague-Dawley rats inoculated ip with 20, 25, or 30 mg/kg 5,6-benzoflavone (BF). The rats were sacrificed at 24-hr intervals beginning on day 1 and ending on day 4. In the liver, a peak level of AHH activity was reached after 24 hr; in the lung, a peak level was reached after 48 hr and it remained stable for about 10 days. The alterations in lung enzyme levels were attributed to passage of BF from the abdominal cavity to the lung by the lymphatic system. (13 refs)

78-3768 **Nuclear Metabolism of Polycyclic Hydrocarbons and Interaction of Polycyclic Hydrocarbons with Nuclear Components.** (Eng) Bresnick, E. (Univ. Vermont Coll. Medicine, Burlington, VT, 05401). *Adv Enzyme Regul* 16: 347-361; 1978.

The ability of the nucleus to activate polycyclic hydrocarbons was investigated in male Sprague-Dawley rats and male mice of various strains treated ip with 20 mg/kg 3-methylcholanthrene (MC) or corn oil. Twenty-four hours later, the animals were killed and the nuclei isolated by centrifugation. The nuclei were incubated with 2 μg of benzo(a)pyrene (BP) and examined by histofluorescence for BP metabolites. Nuclear aryl hydrocarbon hydroxylase (AHH) was present in the nuclear fraction at 15%-20% of the level found in the microsomal fraction. Cytochrome P_{450} was also present within the nucleus, and both AHH and hemopigments were inducible by MC treatment. Rat liver nuclei were incubated with ^{14}C-BP or ^{3}H-(±)trans-BP-7,8-dihydrodiol (^{3}H-BP-7,8-dihydrodiol) in the presence of an NADPH generating system. Prior administration of MC to the rats stimulated the total nuclear metabolism 11-fold. BP was oxidized to the 9,10-, 4,5-, and 7,8-dihydrodiols, the 3,6- and 1,6-quinones, and the 3- and 9-phenols, and BP-7,8-dihydrodiol formation was enhanced 29-fold. The nuclei were also able to produce BP diol epoxides 1 and 2 from BP-7,8-dihydrodiol; MC pretreatment increased this nuclear activity fourfold. Incubation of ^{3}H-BP with liver nuclei in an NADPH-generating system also resulted in aralkylation of DNA, histones, and nonhistone components; prior MC treatment stimulated the aralkylation of these macromolecules. The alkylated deoxyribonucleosides produced after enzymatic digestion of the incubated DNA were separated by Sephadex LH-20 chromatography. Two peaks of radioactivity noted after incubation with BP, but only one major peak was noted after incubation with the diol derivative. It is suggested that the nuclear metabolism of BP and the subsequent alkylation of the DNA may be related to mutagenesis and/or carcinogenesis. (35 refs)

78-3769 **Appraisal of Fluorimetric Assay of Aryl Hydrocarbon (Benzo(α)pyrene) Hydroxylase in Cultured Human Lymphocytes.** (Eng) Trieff, N. M. (Environmental Toxicology Dept. Preventive Medicine and Community Health, Univ. Texas Medical Branch, Galveston, TX, 77550); Cantelli Forti, G.; Smart, V. B.; Kempen, R. R.; Kilian, D. J. *Br J Cancer* 38(2): 335-338; 1978.

Problems inherent in the fluorimetric determination of aryl hydrocarbon hydroxylase (AHH) activity in human lymphocytes were examined. Six simulated experiments were performed according to the procedure developed by Kellerman and coworkers except that lymphocytes were omitted and generally tritiated benzo(a)pyrene (BP) was used. It was shown that 11.72% of the total radioactivity ended up in the NaOH phase, but the method was developed to ensure that no BP, only 3-BPOH, was being extracted by the NaOH. As the BP fluorescence spectrum has one peak with a wavelength max at 522 nanometers, the same as that for 3-BPOH, there is substantial interference of BP in the measurement of the fluorescence intensity of 3-BPOH, especially at low 3-BPOH concentrations and at small slit widths. The photochemical instability of BP, 3-BPOH, and other metabolites may lead to additional errors. (25 refs)

78-3770 **Aryl Hydrocarbon Hydroxylase in Persons with Lung or Laryngeal Cancer.** (Eng) Ward, E. (Dept. Res. Medicine, Univ. Pennsylvania, Philadelphia, PA, 19104); Paigen, B.; Steenland, K.; Vincent, R.; Minowada, J.; Gurtoo, H. L.; Sartori, P.; Havens, M. B. *Int J Cancer* 22(4): 384-389; 1978.

Aryl hydrocarbon hydroxylase inducibility was measured in cultured lymphocytes of 59 cancer patients (32 lung and 27 laryngeal) whose tumors were completely resected 1-10 yr prior to testing and who were considered disease-free. In these patients, AHH inducibility should not have been affected by the disease state. The mean inducibility ratio was 3.2 for the lung cancer patients, 2.96 for the laryngeal cancer patients, and 3.29 for controls. Induced enzyme activity was also similar for patients and controls: 0.25 picomole of 3-hydroxybenzo(a)pyrene/min/10 μg DNA for patients with laryngeal and lung cancer and 0.27 for controls. Thus, no shift toward higher AHH inducibility was observed in patients who had lung or laryngeal cancer compared with controls. (21 refs)

78-3771 **Control of Benzo(a)Pyrene (BP)-induced Mammalian Cell Mutagenesis and Cytotoxicity by Exogenous Enzyme Fractions (Meeting Abstract).** (Eng) Schechtman, L. M. (Dept. Biochemical Oncology, Microbiological Associates, Bethesda, MD, 20016); Kouri, R. E. *Mutat Res* 53(2): 258-259; 1978. (1 ref)

78-3772 **Stimulatory Effect of Cigarette Smoke on the Metabolism and Covalent Binding of Benzo(a)-pyrene in the Trachea of the Rat.** (Eng) Simberg, N. (Dept. Physiology, Univ. Turku, SF-20520 Turku 52, Finland); Uotila, P. *Int J Cancer* 22(1): 28-31; 1978.

The effect of cigarette smoke on the activities of enzymes involved in benzo(a)pyrene (BP) metabolism was investigated in male Wistar rats, along with the degree of covalent binding of BP in the rat trachea. The rats were exposed to the smoke of five commercial filter cigarettes for 1 hr daily, for 1 or 10 days (Group A and B, respectively). Aryl hydrocarbon hydroxylase (AHH) activity was increased in the tracheas of Groups A and B rats, reaching a max 12 hr after the last exposure to 320% and 290% of controls, respectively. However, this activity returned to control levels within 24 hr. At 12 hr after the last exposure, AHH activity in the pulmonary microsomes was 560% of controls in both groups, and it was still increased (360%) at 24 hr. Concomitantly with the increase in AHH activity, the amounts of covalently bound metabolites of BP were increased twofold in the nucleic acid and protein fractions of the tracheas of Group A rats. There was no significant changes in tracheal epoxide hydratase activity in both groups. Repeated exposures slightly increased the activity of uridine diphosphate-glucuronosyltransferase in both the trachea and lung. The results indicate that the metabolism of polycyclic hydrocarbons present in cigarette smoke is enhanced in the respiratory tract after cigarette smoke exposure. (28 refs)

78-3773 **Longevity, Selective Mortality, and Competitive Risks in Relation to Chemical Carcinogenesis.** (Eng) Hammond, E. C. (Dept. Epidemiology and Statistics, American Cancer Society, 777 Third Ave., New York, NY, 10017); Garfinkel, L.; Lew, E. A. *Environ Res* 16(1/3): 153-173; 1978.

Male cigarette smokers and nonsmokers were compared periodically with respect to longevity, total death rates, deaths from cancer (all sites combined), and deaths from cancer of three specific sites: lung, pancreas, and bladder. The data were obtained through questionnaire surveys of men in 22 states, the starting date for the analyses being July 1, 1960, and the ending dates June 30, 1975, for men born in 1887 or earlier and June 30, 1971, for men born later than 1887. The findings were compared with the results calculated for three hypothetical types of cigarettes: LCA, which induce the same lung cancer rates as ordinary cigarettes but have no other effects; BPCA, which increase death rates from bladder and pancreatic cancer; and CA, which yield the same age-specific death rates from cancer of every site and type as ordinary cigarettes. Life expectancy at age 40 was 37.85 yr for nonsmokers, 34.87 yr for light smokers, and 30.79 yr for heavy smokers. The proportion of men living to age 65 was 86.04% for nonsmokers, 79.61% for light smokers, and 70.55% for heavy smokers. The proportions of men living to age 85 were 29.12%, 20.15%, and 9.7%, respectively, for the three groups. The mean ages at death from cancer were 74.93 for nonsmokers, 73.66 for light smokers, and 70.83 for heavy smokers. CA smokers had the same age-specific cancer death rates as ordinary cigarette smokers; LCA smokers, the same age-specific lung cancer death rates as ordinary smokers; BPCA smokers, the same bladder and pancreas death rates as ordinary smokers. Otherwise, the death rates in these three groups were the same as those for nonsmokers. (no refs)

78-3774 **Pathologic Changes in the Lungs of Mice after Inhalation of Cigarette Smoke.** (Cro) Kambic, V. (Otorinolaringoloska klinika, Ljubljana, Zaloska 2, Yugoslavia); Radsel, Z.; Jutersek, A. *Plucne Bolesti Tuberk* 29(3/4): 181-185; 1977.

A study was made of pathological changes in the lungs of 42 male mice exposed to cigarette smoke for various lengths of time over a 10-wk period. The animals were sacrificed at the end of the experiment. Microscopically, there were pulmonary changes in all animals exposed longest to the smoke, but in only 2/7 animals least exposed. The changes included peribronchitis, bronchitis, pneumonia and pulmonary abscess. Normal epithelium was found in the low-exposure groups, but thickened epithelium, abnormal cilia, and loss of the cilia were seen in the high-exposure groups. The incidence and degree of the changes correlated with the degree of exposure. With prolonged exposure, these changes are believed to be capable of developing into precancerosis and carcinoma. Changes in the pharynx and larynx were less marked. (8 refs)

78-3775 **Determination of Polycyclic Aromatic Hydrocarbons in the Air and in the Work Environment.** (Ger) Otto, J. (Arbeitshygieneinspektion des Rates des Bezirkes, Predigerstrasse 6, DDR-50 Erfurt, E. Germany); Schmidt, E. *Z Gesamte Hyg* 24(8): 584-587; 1978.

A gas chromatographic method for determining polycyclic aromatic hydrocarbons in the air is described. A sample size of 5 μl was optimal. With the aid of a flame ionization detector, the detection limits were 0.005 μg for fluorene and anthracene, 0.013 μg for benzo(a)pyrene, and 0.025 μg for benzo(a)fluorene. The av error was 10%. (no refs)

78-3776 **Embryotoxic Effects of Benzene and Its Methyl Derivatives: Toluene, Xylene.** (Eng) Hudak, A. (Dept. Experimental Pathology, State Inst. Occupational Health Budapest, H-1450 Budapest P.O.B. 22, Hungary); Ungvary, G. *Toxicology* 11(1): 55-63; 1978.

The teratogenic and embryotoxic effects of benzene, toluene, and xylene were determined in CFY rats and CFLP mice. The rats were exposed to inhalation of (a) 1,000 mg/m^3 benzene, 1,500 mg/m^3 toluene, or 1,000 mg/m^3 xylene for 24 hr/day from days to 14 of pregnancy; (b) 1,500 mg/m^3 toluene for 24 hr/day from days 1 to 8 of pregnancy, or (c) 1,000 mg/m^3 toluene for 8 hr/day from days 1 to 21 of pregnancy. The mice were exposed to inhalation of 500 mg/m^3 toluene for 24 hr/day from days 6 to 13 of pregnancy. Untreated animals and groups inhaling pure air served as controls. None of the solvents were teratogenic; ie, the incidence of malformations did not change as a result of exposure. However, the incidence of skeletal anomalies (extra ribs, fused sternebrae) was increased with all three solvents. Benzene and toluene also caused considerable retardation of fetal development. The growth-retarding effect of toluene on fetal development in early pregnancy is of particular importance from the point of view of occupational exposure. (32 refs)

78-3777 **Analysis of Sensitizing Effect of Benzene Administered Simultaneously in Water and in Air.** (Rus) Tepikina, L. A. (A. N. Sysin Inst. General and Communal Hygiene, Moscow, USSR); Gordeeva, M. S. *Gig Sanit* (3): 23-27; 1978.

The sensitizing effect of benzene was studied in random-bred albino rats who were exposed simultaneously to benzene in their drinking water (45.0, 9.0, 1.5 mg/kg) and by inhalation

(15.0, 6.63, 0.51 mg/m^3) for up to 100 days. Sensitization was measured by a microprecipitation reaction, a passive hemagglutination reaction, and by skin allergy tests. Positive immunologic reactions were detected on days 21-50 of the experiment, depending on dose. (9 refs)

78-3778 **Followup Study on the Mortality and the Development of Leukemia in 44 Pancytopenic Patients with Chronic Exposure to Benzene.** (Eng) Aksoy, M. (Buyukciflik sokak 10/2 Ozler, ap., Tesvikiye, Istanbul, Turkey); Erdem, S. *Blood* 52(2): 285-292; 1978.

Further evidence of the leukemogenic effect of benzene (BZ) in humans was obtained from a 2- to 17-yr follow-up study of 44 patients with pancytopenia (PCP) who had been exposed occupationally to 150-650 ppm BZ in various adhesives for 4 mo-15 yr (mean, 6.7 yr). The BZ level in the adhesives ranged from 9% to 88%, and daily exposure ranged from 15 min to 8 hr. Thirty-four patients worked in shoe factories. Complete remission of PCP was obtained in 23 patients, but 21 died, 14 due to complications of PCP, 6 following the development 6 mo-6 yr later of leukemia, and 1 due to myeloid metaplasia. The mean age and duration of exposure were significantly higher in the 21 patients with a fatal outcome (36.0 yr and 93.62 mo, respectively) than in the 23 complete remission patients (26.87 yr, 65.43 mo). Nevertheless, except for the mean neutrophil values 1.51 x 10^9/liter for the remission patients, 0.96 x 10^9/liter for the patients that died), the findings in the peripheral blood, including HbF and HbA$_2$ levels, could not be correlated with the outcome of the PCP. However, one patient who had a 0.67% level of HbA$_2$ and a 48% level of HbF during the PCP period developed preleukemia 9 mo later. This observation suggests that low levels of HbA$_2$ with or without high levels of HbF during PCP may be a sign of leukemia. Twenty-one patients, 5 of whom developed leukemia, had a hypocellular bone marrow; 16 of these patients died. Only 1/13 patients with normocellular bone marrow died. (31 refs)

78-3779 **Clastogenic Effects of Styrene Exposure on Bone Marrow Cells of Rat.** (Eng) Meretoja, T. (Dept. Industrial Hygiene and Toxicology, Inst. Occupational Health, Haartmaninkatu 1, SF-00290 Helsinki 29, Finland); Vainio, H.; Jarventaus, H. *Toxicol Lett* 1(5/6): 315-318; 1978.

Male Wistar rats were exposed to 300 ppm styrene in air for 2-11 wk (6 hr/day, 5 days/wk) to determine its effects on bone marrow cells. The chromosome aberration rate increased significantly between 8 and 9 wk of exposure and remained at this level to the end of the test. Aberrant cell incidence ranged from 8% to 12% (1-6% in controls). Polyploid cells were noted exclusively in exposed animals, and they were found in every sample from animals exposed for 11 wk. (8 refs)

78-3782 **Metabolism of the Proximate Carcinoge
1′-Hydroxysafrole and the Isomer 3′-Hydro
yisosafrole.** (Eng) Peele, J. D. (Dept. Lab. Medicine, Medic
Univ. South Carolina, 80 Barre St., Charleston, SC, 2940
Oswald, E. O. *Bull Environ Contam Toxicol* 19(4): 396-40
1978.

The metabolism of the proximate carcinogen 1′-hydroxys
frole (HS) and the isomer 3′-hydroxyisosafrole (HIS) was i
vestigated in the rat. The neutral urinary extracts from ra
inoculated with HS contained the unmetabolized compou
and HIS, along with 3,4-methylenedioxyphenyl vinyl keto
and two other neutral metabolites that were not fully chara
terized. The basic urinary fraction of rats given HS contain
the dimethylamino and piperidyl Mannich base metabolite
The only observed acidic metabolite was 3,4-methylenedio
yhippuric acid. The neutral urinary extract from rats give
HIS contained the unmetabolized parent compoun
3,4-methylenedioxyacetophenone, and traces of HS. The ba
ic fraction contained no metabolites. The acidic fraction co
tained 3,4-methylenedioxyacetophenone and 3′-(3,4-m
thylenedioxyphenyl)-3′-hydroxypropionic acid. In additio
traces of piperonylic acid and 3,4-methylenedioxyhippur
acid were present. A mechanism for the carcinogenic actio
of HS is offered that supports the electrophilic theory of ca
cinogenesis and associates chemical reactivity with biologic
response. The mechanism involves stabilization of a carbon
um ion intermediate by the resonance effect of the methylen
dioxy group. This resonance stabilization could increase t
electrophilicity of the molecule, allowing it to attack tiss
nucleophiles. (12 refs)

78-3783 **2,3,7,8,-Tetrachlorodibenzo-p-dioxin as Coca
cinogen Causing 3-Methylcholanthrene-initia
ed Subcutaneous Tumors in Mice Genetically "Nonrespo
sive" at *Ah* Locus.** (Eng) Kouri, R. E. (Dept. Biochemic
Oncology, Microbiological Associates, Bethesda, M
20016); Rude, T. H.; Joglekar, R.; Dansette, P. M.; Jerin
D. M.; Atlas, S. A.; Owens, I. S.; Nebert, D. W. *Cancer R*
38(9): 2777-2783; 1978.

The purpose of this study was to determine whether 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), at a dose (100 μg/kg ip or sc) sufficient to induce aryl hydrocarbon hydroxylase (AHH) activity and cytochrome P_1-450 in genetically nonresponsive DBA/2 mice would enhance the susceptibility of these mice to 3-methylcholanthrene (3-MC) tumorigenesis. TCDD alone ip killed 30%-70% of the animals in each group of DBA/2 or responsive C57BL/6 mice, but it produced no tumors in survivors 36 wk later. TCDD given to C57BL/6 mice ip 2 days prior to or simultaneously with sc 3-MC did not affect the 3-MC carcinogenic index (which is about 60 in these mice). TCDD given to DBA/2 mice ip 2 days prior to sc 3-MC increased the carcinogenic index slightly (from 5 to 10; in these mice, the carcinogenic index of 3-MC alone is 1). When TCDD was injected simultaneously (sc, in the same vehicle) with 3-MC into DBA/2 mice, the carcinogenic index was increased markedly (from 5 to 38). In this test system, therefore, TCDD appeared to be carcinogenic. However, it is concluded that TCDD is a cocarcinogen. Its proposed mechanism of action is the induction of AHH activity and the associated P_1-450 at the site of inoculation of 3-MC in genetically nonresponsive mice, thereby resulting in more efficient metabolic conversion of 3-MC to the (proximal or) ultimate carcinogen. (39 refs)

78-3784 **Correlation Between Carcinogenicity and Polarographic Reducibility of Some N-substituted Derivatives of 4-Aminoazobenzene.** (Eng) Carruthers, C. (Orchard Park Labs., Roswell Park Memorial Inst., Buffalo, NY, 14263). *Indian J Cancer* 15(1): 49-52; 1978.

The polarographic behavior of six carcinogenic and noncarcinogenic derivatives of 4-aminoazobenzene (4-AAB) was investigated in buffer-ethanol solns at pH 2.6, 4.8, 6.8, 8.2, 9.5, and 11.0, to determine whether there is a correlation between carcinogenicity and polarographic reducibility. The half-wave potential of the noncarcinogens 4-benzylmethyl-AAB, 4-diethyl-AAB, and 4,β-hydroxyethylmethyl-AAB and the carcinogens 4-ethylmethyl-AAB, N-methyl-AAB, and 3′-chloro-4-dimethyl-AAB was essentially the same at any given pH, and it was comparable to that of 4-AAB, 4-dimethyl-AAB, and 3′-methyl-4-dimethyl-AAB (found previously). The results showed that variation in the substituents at the N-position did not appreciably affect the half-wave potential of 4-AAB. (13 refs)

78-3785 **Electrophilic Reactivity and Mutagenicity of Ring-Methyl Derivatives of N-Acyloxy-N-methyl-4-aminoazobenzene and Related Azo Dyes.** (Eng) Degawa, M. (Dept. Hygienic Chemistry, Pharmaceutical Inst., Tohoku Univ., Aobayama, Sendai 980, Japan); Miyairi, S.; Hashimoto, Y. *Gann* 69(3): 367-374; 1978.

The N-hydroxy, N-benzyloxy, and N-acyloxy derivatives of N-methyl-4-aminoazobenzene (MAB), 3′-methyl-MAB, and 4′-methyl-MAB, dyes that have different carcinogenic activities in rats, were synthesized and the electrophilic reactivity and mutagenicity of the parent dyes and the derivatives were compared. The three parent dyes did not react with amino acids, proteins, or DNA; the N-hydroxy derivatives showed slight reactivity with all these substances except for cysteine. The mutagenicity of these dyes towards *Salmonella typhimurium* TA98 and TA100 was expressed only in the presence of the 9,000-*g* supernatant of a rat liver homogenate (S-9 mix), and the 3′-methyl or 4′-methyl substituent did not affect the mutagenic activity of the parent dyes. In contrast, the N-acetoxy and N-benzoyloxy derivatives of the three dyes showed a high degree of reactivity with amino acids, proteins, and DNA, and they were strongly mutagenic toward the bacteria without S-9 mix. No significant differences were observed among these derivatives either in their electrophilic reactivity or mutagenicity. These findings suggest that neither the rate of metabolic activation to ultimate metabolites by liver enzymes nor the electrophilic and mutagenic activities of the N-acyloxy and N-benzoyloxy derivatives were related to the hepatocarcinogenicity of MAB, 3′-methyl-MAB, and 4′-methyl-MAB. Other possible factors influencing the carcinogenicity of MAB homologs are discussed. (18 refs)

78-3786 **Appearance of Intestinal Type of Tumor Cells in Hepatoma Tissue Induced by 3′-Methyl-4-dimethylaminoazobenzene.** (Eng) Yoshida, Y. (La Jolla Cancer Res. Foundation, P.O. Box 1376, 417 Coast Blvd. S., La Jolla, CA, 92038); Kaneko, A.; Chisaka, N.; Onoe, T. *Cancer Res* 38(9): 2753-2758; 1978.

Hepatomas induced in male Wistar rats by 3′-methyl-4-dimethylaminoazobenzene (3′-Me-DAB: 0.06% of diet for 14 wk) were investigated both morphologically and biochemically. The most prominent histological pattern was that of undifferentiated carcinoma. Although this type of carcinoma, histologically, appeared to be due to a uniform population of cells, electron microscopic examination revealed that the tissue was composed of many types of cells, including cells that contained either the brush border or the mucous droplets seen in goblet cells. In addition, tumor cells that contained serotonin like granules were noticed. An electrophoretogram of alkaline phosphatase activity in the tissue extract of this type of carcinoma revealed distinctly the presence of its intestinal-type isoenzyme. These findings show that carcinomas induced by 3′-Me-DAB contain cells differentiated toward hepatocytes or cholangiolar cells and those differentiated toward intestinal epithelial cells. (19 refs)

78-3787 **Hepatoma Induction in the Rat by the Subcutaneous Administration of Powdered 3′-Methyl-p-dimethylaminoazobenzene.** (Eng) Carruthers, C. (Orchard Park Labs., Roswell Park Memorial Inst., 666 Elm St., Buffalo, NY, 14263); Baumler, A.; Pauly, S. *Experientia* 34(6): 788; 1978.

Hepatomas were induced in male Fischer rats with the use of a procedure that does not require special facilities for formulating diets containing azocarcinogens. Powdered 3′-methyl-p-dimethylaminoazobenzene (3′-Me-DAB; 200 mg) was evenly distributed under skin flaps created by a 5- to 6-cm abdominal incision in 6- to 8-mo-old rats. This procedure was repeated every 30 days for 3-7 mo. The rats tolerated the sc application of powdered 3′-Me-DAB very well. In four experiments, 67%-82% of rats developed liver tumors (mixtures of hepatocellular carcinomas and cholangiocarcinomas). It is concluded that the sc procedure for inducing liver tumors should be useful when facilities for incorporating 3′-Me-DAB into the diet are unavailable. However, for personal safety, an isolated laboratory should be used for the monthly 3′-Me-DAB administration. (7 refs)

78-3788 **In Vitro Evaluation of Some Derivatives of the Carcinogen Butter Yellow: Implications for Environmental Screening.** (Eng) Ashby, J. (Central Toxicology Lab., Imperial Chemical Industries Ltd., Alderley Park, Macclesfield, Cheshire, England); Styles, J. A.; Paton, D. *Br J Cancer* 38(1): 34-50; 1978.

The rat liver carcinogen 4-dimethylaminoazobenzene (Butter Yellow, DAB), several structural analogs, benzidine, and benzidine-3,3′-disulfonic acid were tested in vitro for their ability to transform BHK21/C13 cells in the presence of an Aroclor 1254-induced rat liver S-9 mix. Positive results were obtained for DAB; a mixture of DAB and azobenzene; 9-phenylazojulolidine; N-methyl-5-phenylazoindoline; DAB-4′-sulfonic acid, sodium salt (methyl orange); benzidine, 4-dimethylamino-4′-trifluoromethylazobenzene; 4-diethylaminoazobenzene; 4-diethylamino-4′-ethylazobenzene; 4-aminoazobenzene; and 4-aminoazobenzene-4′-sulfonic acid. 3-Methyl-DAB, azobenzene, 3,5-dimethyl-DAB, benzidine-3,3′-disulfonic acid, and 3,5-dimethyl-4-aminoazobenzene were negative. It is suggested that the promotion of DAB-induced transformation by azobenzene is the result of the latter acting as a competitive substrate for one of the enzymes that detoxify the former. These findings are correlated with those of previous experiments. This assay cannot be relied on to predict the in vivo potency of carcinogens. (56 refs)

78-3789 **Biochemical Features of Liver from Low- and High-Cancer Mouse Strains and of Primary Spontaneous Hepatomas. Distribution of Hepatic Enzymes in Induced and Spontaneous Hepatomas and in Normal Liver of Low- and High-Cancer Mouse Strains.** (Rus) Gobeev, V. N. (Dept. Biochemistry, Patrick Lumumba Univ., Moscow, USSR); Khripach, L. V.; Berezov, T. T. *Vopr Med Khim* 24(4): 533-539; 1978.

The activity of various hepatic enzymes was studied in CBA mice with spontaneous hepatomas and in C3HA mice with o-aminoazotoluene(o-AAT)-induced hepatic carcinomas (pills containing o-AAT were implanted sc, approx 1x/mo). Spontaneous hepatomas were detected in 70% of CBA males (compared with 10% of CBA females). Hexokinase (HK) activity was significantly increased in the hepatoma tissue (0.28 IU, compared with 0.11 IU in tumor-free regions of the liver), but cytochrome oxidase (CO) activity was significantly decreased in the hepatomas (1.1 IU, compared with 2.5 IU in the unaffected liver tissue of tumor-bearing animals). Similar changes were detected in C3HA mice with induced hepatomas: the activity of HK and CO in the liver of tumor-bearing animals was 0.37 and 3.1 IU, respectively, compared with 0.11 and 3.6 IU in tumor-free mice. (15 refs)

78-3790 **Responsiveness of Peroxisomal Enzymes of Rat Livers During 3′-Methyl-4-dimethylaminoazobenzene Hepatocarcinogenesis to Clofibrate.** (Eng) Mochizuki, Y. (Dept. Pathology, Cancer Res. Inst., Sapporo Medical Coll., Sapporo 060, Japan); Itabashi, M. *Tumor Res (Sapporo)* 12: 37-46; 1977.

The effect of clofibrate on the activities of the peroxisomal enzymes catalase, D-amino acid oxidase, urate oxidase, and L-α-hydroxy acid oxidase was determined in the livers of male Wistar rats fed a diet containing 0.06% 3′-methyl-4-dimethylaminoazobenzene (3′-Me-DAB). Animals were sacrificed after 10, 13, 15, 17, and 19 wk on the diet; 1% clofibrate was added to the diet 2 wk before sacrifice. Although 3′-Me-DAB depressed catalase activity, clofibrate increased the activity of this enzyme at all time intervals studied. (Preliminary experiments indicated that the induction of catalase by clofibrate was not influenced by the carcinogen.) The highest increase was observed at 13 wk. This suggested that hepatocytes that had degenerated early after 3′-Me-DAB administration were undergoing maturation. The minimum increase in catalase activity in response to clofibrate was observed at 19 wk; this indicated that the lesions that were not responsive to clofibrate had increased in number. Foci that were not responsive to clofibrate were noted as early as week 10; therefore, changes essential to hepatoma formation had occurred by this time. The hepatoma precursor lesions were increased by 17-19 wk. The activity of D-amino acid oxidase was decreased by clofibrate at all times. Neither urate oxidase nor L-α-hydroxy acid oxidase activities were affected by clofibrate during carcinogenesis. (69 refs)

78-3791 **Enhancing and Inhibitory Effects of Some Stilbene and Steroid Compounds on Induction of Hepatoma in Rats Fed 3′-Methyl-4-(dimethylamino)azobenzene.** (Eng) Akao, M. (Res. Inst. Chemobiodynamics, Chiba Univ., Inohana 1-8-1, Chiba 280, Japan); Kuroda, K. *Gann* 69(3): 375-382; 1978.

The enchancement or inhibition of hepatoma induction in 3′-methyl-4-(dimethylamino)azobenzene (3′-Me-DAB)-treated male Donryo rats by stilbene, 4-nitrostilbene (NSB), 4,4′-dihydroxystilbene, diethylstilbestrol (DES), 17β-estradiol, and methyltestosterone was studied. Rats were fed a diet containing 0.06% 3′-Me-DAB to a total of 0.5 or 1 g, followed by 0.25 or 0.5 g of test substance in a basal diet. Comparison of the development and yield of hepatomas indicated that NSB and methyltestosterone enhanced 3′-Me-DAB carcinogenesis, whereas DES and 17β-estradiol retarded it. The other substances had no effect on carcinogenesis. The enhancement by NSB and inhibition by DES was correlated with their effect on liver nucleic acid metabolism. Feeding of NSB selectively inhibited the Mn^{2+}-$(NH_4)_2SO_4$-activated RNA polymerase activity of liver nuclei and reduced liver RNA content. These changes were followed by an increase in the incorporation of ip-injected ^{3}H-thymidine into liver DNA. In contrast, feeding of DES increased liver RNA content without affecting the RNA polymerase activity of liver nuclei; and it also increased incorporation of ^{3}H-thymidine into DNA. Moreover, the increased incorporation ceased when DES was removed from the diet. (19 refs)

78-3792 **Squamous Cell Dysplasia and Carcinoma In Situ of the Cervix and Vagina after Prenatal Exposure to Diethylstilbestrol.** (Eng) Robboy, S. J. (Dept. Pathology, Massachusetts General Hosp., Boston, MA, 02114); Keh, P. C.; Nickerson, R. J.; Helmanis, E. K.; Prat, J.; Szyfelbein, W. M.; Taft, P. D.; Barnes, A. B.; Scully, R. E.; Welch, W. R. *Obstet Gynecol* 51(5): 528-535; 1978.

The prevalence and incidence of squamous cell dysplasia of the vagina and cervix were determined in 1,424 women (aged 13-31 yr) exposed to diethylstilbestrol (DES) in utero. Some of these women had been followed for 6 yr. Six types of squamous cell abnormalities were noted: mature squamous metaplasia, immature squamous metaplasia, mild dysplasia, moderate dysplasia, severe dysplasia, and carcinoma in situ. The prevalence of dysplasia was 2.1%, and the incidence was 0.85/100 person-yr of follow-up. The dysplastic epithelial changes were almost always mild in women with no prior history of dysplasia, and they originated equally in the cervix and vagina. Severe dysplasia and carcinoma in situ were encountered only in those subjects specifically referred because of these abnormalities. The most common problem in diagnosing the squamous cell changes was the misinterpretation of mature and immature metaplastic cells for dysplastic squamous cells. Discordance between biopsy and cytology was commonplace in the detection and follow-up of dysplasia, especially mild forms. There were no instances in which the cytology and biopsy samples from the vagina were both abnormal concurrently. There were five instances in which the initial cervical biopsy specimen and scrape smear were both abnormal. Colposcopically directed biopsies did not increase the frequency of confirmation of cytologic findings. These findings suggest that both cytology and biopsy of abnormal segments of the vagina and cervix remain an integral part of the examination of DES-exposed women. (27 refs)

78-3793 **Angiosarcoma of the Liver Associated with Diethylstilbestrol.** (Eng) Hoch-Ligeti, C. (Registry Experimental Cancer, NCI, Del Ray Bldg., Bethesda, MD, 20014). *JAMA* 240(14): 1510-1511; 1978.

Angiosarcoma of the liver occurred in a 76-yr-old man who had been treated for 13 yr with diethylstilbestrol (3 mg/day) for a well-differentiated adenocarcinoma of the liver. The angiosarcoma was also present in pulmonary and renal arteries. Since in many smaller pulmonary arteries the lumen was completely filled by tumor and surrounding tissue was unaffected, the intima apparently represented a primary site. (8 refs)

78-3794 **Squamous Cell Carcinoma In Situ of the Vagina and Cervix after Intrauterine DES Exposure.** (Eng) Veridiano, N. P. (Dept. Obstetrics and Gynecology, Brookdale Hosp. Medical Center, Linden Blvd. at Brookdale Plaza, Brooklyn, NY, 11212); Tancer, M. L.; Weiner, E. A. *Obstet Gynecol* 52(1, Suppl): 30s-33s; 1978.

Squamous cell carcinoma in situ (CIS) of the cervix and vagina arose in areas of squamous metaplasia that replaced areas of adenosis in two women (20 and 23 yr old) exposed to diethylstilbestrol in utero. Their case reports are presented, along with a summary of data on 201 patients with a history of in utero DES exposure that are currently under observation. Adenosis was detected in 174 patients. In addition to the 2 CIS patients, 15 patients had mild or moderate dysplasia (6, cervix alone; 9, cervix + vagina), and 2 had severe dysplasia of the cervix and vagina. Thus, 19 patients with cervical and/or vaginal intraepithelial neoplasia were seen among 203 patients exposed to DES in utero. However, in only 50% of these 19 patients did a Papanicolaou smear reveal abnormal cells. There appears to be a strong possibility that there is a continuous process beginning with DES exposure and proceeding through the occurrence of adenosis and active squamous metaplasia to dysplastic alteration and, finally, squamous neoplasia. (3 refs)

78-3795 **Stilboestrol and Vaginal Clear-Cell Adenocarcinoma Syndrome.** (Eng) Monaghan, J. M. (Dept. Gynaecological Oncology, Queen Elizabeth Hosp., Gateshead, Tyne and Wear NE9 6SX, England); Sirisena, L. A. *Br Med J* 1(6127): 1588-1590; 1978.

The development of a vaginal clear-cell adenocarcinoma in a 25-yr-old woman who had been exposed in utero to maternal stilbestrol treatment is described. Although this is the first such case to be reported in the UK, 250 cases have been recorded in the literature since 1966. In every case for which a detailed prenatal history was available, stilbestrol had been administered before the 18th week of gestation. The primary presenting symptom was abnormal bleeding or bloodstained intermenstrual discharge, but 28 patients were asymptomatic. The patients ranged in age from 7 to 29 yr, with a peak incidence around 18 yr. Between 1940 and 1971, approximately 7,500 women in the UK were given stilbestrol during pregnancy. In reference to these figures and US registry data, there may be at least 10 latent cases of vaginal adenocarcinoma. The best methods for screening for presymptomatic carcinoma are visualization of the vagina and cervix, cytology of both the vaginal aspirate and cervical scrape, iodine staining, and colposcopy with biopsy of suspicious areas. (3 refs)

78-3796 **Relations Between Bleeding Pattern, Endometrial Histology, and Oestrogen Treatment in Menopausal Women.** (Eng) Sturdee, D. W. (Walsgrave Hosp., Coventry CV2 2DX, England); Wade-Evans, T.; Paterson, M. E.; Thom, M.; Studd, J. W. *Br Med J* 1(6127): 1575-1577; 1978.

The effects of hormone treatment on the endometrium were investigated in 286 English women who had received various regimens of estrogen treatment for an av of 9.7 mo for climacteric symptoms. Two hundred and fifty-seven women had a normal endometrium, 21 had cystic hyperplasia, 7 had adenomatous hyperplasia, and 1 had endometrial adenocarcinoma. The incidence of endometrial hyperplasia was 12% among the 98 women given cyclical unopposed po estrogen treatment, 8% among the 37 patients given an additional 5-day course of progestogen in each cycle, 28% among the 50 women treated with sc estradiol implants and monthly 5-day courses of po progestogen, and 0% among the 102 women on regimens that included 10 or 13 days of progestogen per cycle. Regular withdrawal bleeding during treatment was associated with a lower incidence of endometrial hyperplasia (6%) than unscheduled breakthrough bleeding (28%), but the one patient with carcinoma had experienced only regular bleeding. The risk of developing endometrial carcinoma from estrogen treatment may be reduced by avoiding the use of unopposed estrogen regimens, the addition of > 5 days' treatment with a progestogen, and the recognition that a regular bleeding response to estrogen is no guarantee of a healthy endometrium. (16 refs)

78-3797 **Exposure of Pregnant Mice to Hormones: Effects on the Reproductive Cycles and Organs in Their Female Offspring.** (Eng) Mori, T. (Zoological Inst., Faculty Science, Univ. Tokyo, Bunkyo-ku, Hongo, Tokyo 113, Japan); Bern, H. A.; Mills, K. T. *ICRS Med Sci (Cancer)* 6(7): 275; 1978.

The effect of a single injection of 500 μg estradiol-17β on the offspring of BALB/cfC3H/Crgl and C3H/Tw mice was determined. The former received the hormone on day 15 of pregnancy, the latter on day 12 or 15. Two of 8 BALB/c mice had vaginal lesions by 1 yr, compared with 0/11 controls. In C3H mice, exposure on day 15 resulted in abnormal reproductive cycles and abnormalities in the cervicovaginal epithelium of 3/12 mice, vs 0/8 mice exposed in utero on day 12 and 0/15 controls. It is not known whether the genital tract changes were ovary-dependent or -independent. (5 refs)

78-3798 **Hepatocellular Carcinoma in Young Women on Oral Contraceptives (Letter to Editor).** (Eng) Christopherson, W. M. (Dept. Pathology, Univ. Louisville Sch. Medicine, Louisville, KY, 40201); Mays, E. T.; Barrows, G. *Lancet* 2(8079): 38-39; 1978.

Twenty cases of hepatocellular carcinoma listed in one Kentucky tumor registry are reported. Seventeen of the 20 patients, all women aged 17-46 yr, had taken oral contraceptives for 6-120 mo (av 57 mo). Eleven of the 15 that died had widespread metastases. None of the 20 patients had cirrhosis or fibrosis. (no refs)

78-3799 **Hyperplasia and Prolapse of Hepatocytes into Hepatic Veins During Longterm Methyltestosterone Therapy: Possible Relationships of these Changes to the Development of Peliosis Hepatis and Liver Tumours.** (Eng) Paradinas, F. J. (Dept. of Histopathology, Charing Cross Hosp. and Medical Sch., London, England); Bull, T. B.; Westaby, D.; Murray-Lyon, I. M. *Histopathology* 1(4): 225-246; 1977.

Pathological changes in liver biopsy specimens from 10 patients (4 female transsexuals and 6 impotent males) after they were treated with 150 mg methyltestosterone daily for periods of up to 3 yr and in a hemihepatectomy specimen from a female transsexual who developed a liver adenoma after 37 mo of this treatment are reported. Hepatocyte hyperplasia and mild focal sinusoidal dilatation were found in most cases. In some there were microcysts and a dissociation of hepatocytes. In nine patients, there was an accumulation of hepatocytes between the endothelium and the supporting collagen of hepatic veins that often resulted in partial occlusion of their lumina or disruption of their walls. These vascular changes do not appear to have been reported before. The av length of treatment associated with the development of peliosis was considerably shorter than that associated with tumor development. It is postulated that a single pathological process--hyperplasia--which may be related to the anabolic effect of methyltestosterone, could be partly responsible for the formation of cysts through mechanical obstruction of hepatic veins and for the formation of nodules and tumors. (55 refs)

78-3800 **The Existence of a Benzo(a)pyrene-3,6-quinone Reductase in Rat Liver Microsomal Fractions.** (Eng) Capdevila, J. (Dept. Biochemistry, Univ. Texas Health Science Center at Dallas, 5323 Harry Hines Blvd., Dallas, TX, 75235); Estabrook, R. W.; Prough, R. A. *Biochem Biophys Res Commun* 83(4): 1291-1298; 1978.

Analysis of repetitive-scan difference spectra of incubation mixtures containing liver microsomes from phenobarbital-pretreated rats, benzo(a)pyrene 3,6-quinone (BP 3,6-quinone), and NADPH revealed the rapid reduction of the quinone to a steady-state level of hydroquinone and the subsequent reoxidation of the hydroquinone. This cyclic process results in NADPH oxidation coupled to oxygen reduction and hydrogen peroxide formation. The reduction of the BP 3,6-quinone was not supported by NADPH. The initial rate of the NADPH-supported reaction was inhibited by NADPH+, metyrapone, and anti-NADPH-cytochrome P-450 (*c*) reductase globulin, but not by dicumarol, anaerobiosis, or a gas mixture of carbon monoxide and oxygen (4:1, volume/volume). These results suggest that cytochrome P-450 and its reductase are involved in this reaction. During the steady-state metabolism of BP, the 3,6-quinone is present largely as a diol that may be conjugated to form water-soluble products and excreted. In addition, the reactive oxygen intermediates and semiquinone free radicals formed may have toxic properties or be capable of altering genome function and/or structure. (15 refs)

78-3801 **The Action of Two Sulfhydryl Compounds on the Induction of Sister Chromatid Exchanges (SCEs) by Trenimon in Human Lymphocytes (Meeting Abstract).** (Eng) Gebhart, E. (Institut fur Humangenetik und Anthropologie der Universitat, Bismarckstr. 10, D-8520 Erlangen, W. Germany); Kappauf, H. *Mutat Res* 53(2): 190; 1978. (no refs)

78-3802 **Relation Between the Use of Artificial Sweeteners and Bladder Cancer (Letter to Editor).** (Eng) Connolly, J. G. (Ontario Cancer Treatment and Res. Foundation, Toronto, Ontario, Canada); Rider, W. D.; Rosenbaum, L.; Chapman, J. A. *Can Med Assoc J* 119(5): 408; 1978.

A survey of the environmental and occupational aspects of bladder cancer revealed that 58/341 patients and 130/673 controls used artificial sweeteners. Thus, there was no relation between bladder cancer and consumption of the sweeteners. (no refs)

78-3803 **Saccharin: An Epigenetic Carcinogen/Mutagen?** (Eng) Ashby, J. (Central Toxicology Labs., Imperial Chemical Industries Ltd., Alderley Park, Macclesfield, Cheshire, England); Styles, J. A.; Anderson, D.; Paton, D. *Food Cosmet Toxicol* 16(2): 95-103; 1978.

The carcinogenicity of saccharin (Sa), sodium saccharin (SSa), and 13 related compounds was evaluated in two in vitro tests, and the results were evaluated within the context of the ability of commercial Sa to cause bladder cancer in rats and dominant lethal effects in mice. Five doses (4-2,500 μg/plate) of the test compounds were used in the Salmonella assay. In the cell-transformation assay, baby hamster kidney cells in semisolid agar were exposed to six doses (0.025-2,500 μg/ml) of each compound. Except for 3-dimethylamino-ψ-saccharin (DMASa), all compounds were negative in all four Salmonella testers strains used. DMASa had a positive effect in TA98 and TA100, but these results could not be reproduced. All compounds were negative in the transformation assay and all had a similar low toxicity. The following hypotheses are proposed for the divergence between the in vitro and in vivo findings: (1) an undefined impurity in commercial Sa that is responsible for the carcinogenic effect is unable to produce positive effects in vitro because of its low concentration in the test material; (2) the electrophilic theory of DNA attack linked to the somatic mutation theory of cancer induction may not include all organic carcinogens (Sa is nucleophilic). Based on available evidence, it is suggested that the in vivo effects of commercial Sa are probably due to Sa per se and that they may arise by an epigenetic mechanism. Further, these effects may only be exhibited above a given threshold dose that may be much higher than the "safe" level suggested by analogy with carcinogens operating via a genotypic mechanism. (60 refs)

78-3804 **Saccharin, Cyclamate, and Human Bladder Cancer. No Evidence of an Association.** (Eng) Kessler, I. I. (Dept. Epidemiology and Preventive Medicine, Univ. Maryland Sch. Medicine, 655 W. Baltimore St., Baltimore, MD, 21201); Clark, J. P. *JAMA* 240(4): 349-355; 1978.

The results of a hospital-based case-control study of the possible roles of saccharine and cyclamate in human urinary bladder cancer are reported. The study groups consisted of 519 patients with histopathologically confimed bladder cancer and 519 matched controls (cancer-free patients) from metropolitan Baltimore. All subjects were subjected to an intensive personal interview with respect to smoking habits, occupational history, and use of nonnutritive sweeteners (NNS). The proportions of patients and controls who ever used NNS in any form were the same (39.5%), and the frequency, quantity, or duration of intake of these substances did not differ significantly between the two groups. These normal findings persisted after simultaneous adjustment for the effects of smoking, occupation, age, diabetes mellitus, and several other potentially confounding factors. The failure of the relative risk of bladder cancer to increase with increasing NNS exposure is also inconsistent with an etiologic relationship. However, cyclamates were introduced too recently to permit the detection of carcinogenic effects appearing more than 10 or 15 yr after initial exposure. It is concluded that neither saccharin nor cyclamate is likely to be carcinogenic in man, at least at the moderate dietary levels reported by the patient sample. (18 refs)

78-3805 **Saccharin-induced Sister Chromatid Exchanges in Chinese Hamster and Human Cells.** (Eng) Wolff, S. (Lab. Radiology, Univ. California, San Francisco, CA, 94143); Rodin, B. *Science* 200(4341): 543-545; 1978.

The ability of the sodium salt of saccharin (lot S1022) and purified saccharin to induce sister chromatid exchanges (SCE's) in cultured Chinese hamster ovary cells and human lymphocytes was investigated. In the ovary cells, no growth was noted in cells treated with ≥1.5% S1022 or with > 1.2% pure saccharin. In the lymphocytes, no growth was noted in cells treated with > 0.5% S1022 or pure saccharin. However, both batches of saccharin increased the yield of SCE's in both types of cells. These findings indicate that the weak carcinogen saccharin does induce cytogenetic changes in cultured cells. (14 refs)

78-3806 **Non-mutagenicity of Saccharin (Letter to Editor).** (Eng) Pool, B. (Inst. Toxicology and Chemotherapy, German Cancer Res. Center, Im Neuenheimer Feld 280, 69 Heidelberg, W. Germany). *Toxicology* 11(1): 95-97; 1978.

Assay of the mutagenicity of a relatively pure sample of sodium saccharin (< 10 ppm o-toluolsulfonamide) in *Salmonella typhimurium* TA1535, TA1537, TA98, and TA100 produced negative results. Previous positive responses may have been due to impurities. (10 refs)

78-3807 **The Effect of Chronic Alcohol Intake upon the Hepatic Microsomal Carcinogen-Activation System.** (Eng) Capel, I. D. (Res. Dept., Marie Curie Memorial Foundation, The Chart, Oxted, Surrey RH8 0TL, England); Jenner, M.; Pinnock, M. H.; Williams, D. C. *Oncology* 35(4): 168-170; 1978.

The effect of chronic ethanol (EtOH) administration on the activation and subsequent DNA binding of benzo(a)pyrene (BP) was investigated in TO mice. The effect of EtOH pretreatment on the development of BP-induced tumors was also investigated. Males and females were inoculated ip with 0.2 ml of an aqueous EtOH soln at doses of 0.7, 1.2, 1.5, or 1.8 mg/g on 7 consecutive days. Two days later, the mice were sacrificed and their hepatic microsomes were assayed (Group 1) or they were inoculated ip with 1 mg BP (Group 2). The latter were sacrificed 20 wk later. The third group of males was given 10% (volume/volume) distilled EtOH in the drinking water and sacrificed after 2, 4, or 8 wk. Cytochrome P-450 and aryl hydrocarbon hydroxylase (AHH) levels were reduced in Group 1 mice. Microsomal protein was also significantly reduced at all EtOH concentrations except 1.2 mg/g. In Group 3, the level of microsomal protein decreased initially but after 2 wk it increased until at 8 wk it had recovered to control levels. The cytochrome P-450 level was raised significantly in all Group 3 animals. In both Groups 1 and 3, the binding of BP to DNA was reduced significantly, corresponding to the decrease in AHH activity. Mice pretreated with EtOH and given BP developed more tumors than mice given BP only (8/77 mice vs 1/42). The tumors in the pretreated animals originated in the muscle tissue, but the one that developed in the control group was a mammary tumor. It is hypothesized that the in vivo excretion of carcinogens, which is reduced in animals with EtOH-induced liver damage, is a more important factor in tumor development than the reduction of activation and binding of BP observed in vitro. However, DNA repair mechanisms might also be adversely affected by chronic alcohol intake. (15 refs)

78-3808 **The Effect of Long Term Ethanol Intake on the Hepatic Carcinogen Metabolising Enzyme Systems of Mice.** (Eng) Capel, I. D. (Res. Dept., Marie Curie Memorial Foundation, Chart, Oxted, Surrey RII8 0TL, England); Williams, D. C. *ICRS Med Sci (Cancer)* 6(7): 297; 1978.

Male TO mice were maintained on a diet containing 1% or 10% ethanol for up to 24 and 32 wk, respectively. Both diets increased the microsomal protein and cytochrome P_{450} levels. The lower ethanol concentration induced aryl hydrocarbon hydroxylase (AHH) activity and increased the DNA binding of benzo(a)pyrene (BP). The higher concentrations resulted in an initial decrease in AHH levels followed by an increase to values greater than controls; BP binding was decreased, and it recovered to control levels only after 32 wk. (8 refs)

78-3809 **Nutrition, Alcohol, and Esophageal Cancer.** (Fre) Tuyns, A. J. (Centre International de Recherche sur le Cancer, 150, cours Albert-Thomas, F69372 Lyon Cedex 2, France); Pequignot, G.; Jensen, O. M. *Bull Cancer (Paris)* 65(1): 59-64; 1978.

A study in Brittany, France, compared diet and alcohol and tobacco consumption in a group of 200 men with esophageal cancer with those controls. No major deficiencies were found, either in quantity or quality, in the diet of the cancer group. A definite correlation was observed between alcohol consumption and the incidence of esophageal cancer. Smokers also had a higher incidence of this cancer. A dose-response relationship existed independently for alcohol and tobacco and the incidence of cancer; however, the use of both had a cumulative effect on incidence. Surveys of the role of dietary factors in esophageal cancer in other areas, such as Iran, are reviewed. (24 refs)

78-3810 **Effect of Ethanol and Vinyl Chloride on the Induction of Liver Tumors: Preliminary Report.** (Eng) Radike, M. J. (Univ. Cincinnati, Inst. Environmental Health, Kettering Lab., Cincinnati, OH, 45267); Stemmer,

K. L.; Brown, P. G.; Larson, E.; Bingham, E. *Environ Health Perspect* 21: 153-155; 1977.

A preliminary report of the effect of ethanol on vinyl chloride (VC) carcinogenicity in 320 male Sprague-Dawley rats is presented. Equal numbers of rats were divided into four groups. Group 1 received a normal diet and breathed filtered air for life. Group 2 received a normal diet plus 5% ethanol in the drinking water and breathed filtered air for life. Group 3 received a normal diet but breathed 600 ppm VC 4 hr/day, 5 days/wk, for 1 yr. Group 4 received a normal diet plus ethanol starting 4 wk before VC exposure. The ethanol exposure lasted until the animal died or was sacrificed. Sixty weeks after the first exposure to VC, 55 rats had died or had been sacrificied. No tumors were noted in eight Group 1 animals that had died. Of six dead Group 2 animals, one had a kidney tumor. Of 13 dead Group 3 animals, 5 had liver tumors (2 of them being angiosarcomas) and 2 had lung tumors. Of 28 dead Group 4 animals, 21 had 26 liver tumors (5 angiosarcomas) and 2 had kidney tumors. These preliminary findings suggest a synergism between VC inhalation and ingested alcohol in tumorigenesis. (6 refs)

78-3811 **Development of Hepatic Angiosarcoma in Man Induced by Vinyl Chloride, Thorotrast, and Arsenic. Comparison with Cases of Unknown Etiology.** (Eng) Popper, H. (Stratton Lab. Liver Disease, Mount Sinai Sch. Medicine, City Univ. New York, New York, NY); Thomas, L. B.; Telles, N. C.; Falk, H.; Selikoff, I. J. *Am J Pathol* 92(2): 349-376; 1978.

Human hepatic angiosarcomas that occurred following exposure to vinyl chloride, Thorotrast, or arsenic (medicinal and industrial) and cases, including those in children, of unknown etiology were studied to establish diagnostic criteria and evolutionary features. The uniform evolution suggests that there is also an environmental factor in the cases of unknown etiology. The precursor stage is characterized by areas of combined hyperplasia of hepatocytes and a variety of sinusoidal and perisinusoidal cells associated with an excess of reticulin and with sinusoidal dilatation. Silver stainings indicated reticulum formation by the perisinusoidal cells, presumably the lipocytes. The hepatocytic proliferation suggested a hepatocarcinogenic, but usually not fully expressed, potential. The mixed hyperplasia of the various sinusoidal cells proceeded to an overgrowth of angiosarcoma cells, presumably derived from endothelial cells. In early stages they were usually in contact with hepatocyte (intralobular growth). A trabecular arrangement resulted from loosening of the lobular plate arrangement by dilatation of sinusoids, leading to primary peliosis. With disappearance of the hepatocytes, various growth patterns developed, terminating in nodular, solid angiosarcoma composed of either spindle-shaped or polyhedral cells that underwent necrosis or hemorrhage (secondary peliosis). The interaction between hepatocytes and sinusoidal cells requires elucidation. (110 refs)

78-3812 **Acute Exposure to VCM: a Cytogenetic Study of Two Workers (Meeting Abstract).** (Eng) Hansteen, I. L. (St. Josephs Hosp., Porsgrunn, Norway). *Mutat Res* 53(2): 196; 1978. (no refs)

78-3813 **Effects of Vinyl Chloride Exposure Alone and in Combination with Trypan Blue--Applied Systematically During All Thirds of Pregnancy--on the Fetuses of CFY Rats.** (Eng) Ungvary, G. (Dept. Experimental Pathology, State Inst. Occupational Health Budapest, H-1450 Budapest P.O.B. 22, Hungary); Hudak, A.; Tatrai, E.; Lorincz, M.; Folly, G. *Toxicology* 11(1): 45-54; 1978.

The teratogenic and embryotoxic effects of vinyl chloride and/or trypan blue were investigated in CFY rats. VC was found in the fetal and maternal blood as well as in the amniotic fluid of pregnant CFY rats exposed to an atomospheric concentration of 5,500, 18,000, or 33,000 mg/m^3 VC for 2.5 hr on gestation day 18, indicating the permeability of the placenta to the agent. Investigation of the offspring of pregnant rats exposed continuously to 4,000 mg/m^3 VC during the first, second, or last trimester showed that VC has no teratological or embryotoxic effects when applied during the second or last trimester. However, exposure to VC during the first trimester resulted in an increased fetal mortality and in the manifestation of embryotoxic effects. Fetal losses and the induction of CNS malformations due to trypan blue (50 mg/kg sc on gestation days 7 and 8) were not potentiated by 4,000 mg/m^3 VC. Occupational exposure of women of childbearing age may be hazardous. (34 refs)

78-3814 **Vinyl Chloride and Pulmonary Cancer (Letter to Editor).** (Eng) Wagoner, J. K. (Office Assistant Secretary for OSHA, 200 Constitution Ave., Room N3660, Washington, DC, 20210). *J Environ Pathol Toxicol* 1(3): 361-362; 1978.

In a previous article, the development of an undifferentiated adenocarcinoma of the bronchus in a 45-yr-old organic chemist was attributed to a 2-yr exposure to bis(chloromethyl)ether. This claim was made in spite of the patient's long-term involvement in vinyl chloride (VC) research. Since numerous animal and human studies have indicated a link between VC exposure and pulmonary cancer, it is suggested that VC was the agent that caused the tumor. (10 refs)

78-3815 **Study of the Teratogenic and Embryotoxic Effects of Vinyl Chloride in CFY Rats.** (Hun) Ungvary, Gy. (Orszagos Munka- es Uzemegeszsegtani Intezet, Budapest, Hungary); Hudak, A.; Tatrai, E.; Lorincz, M.; Folly, G. *Egeszsegtudomany* 21(4): 363-369; 1977.

Inhalation of vinyl chloride (4,000 mg/m^3) between the 8th and 14th days of pregnancy increased the absolute and relative wt of the liver of pregnant CFY rats significantly, but there was no significant increase in resorption, embryonal mortality, and developmental anomalies. In addition, vinyl chloride was found in the maternal and fetal blood and amniotic fluid following exposure of the mothers to 5,500-33,000 mg/m^3 vinyl chloride for 2.5 hr on the 18th day of pregnancy. (31 refs)

78-3816 **Pharmacokinetics of Vinylidene Chloride in the Rat.** (Eng) McKenna, M. J. (Toxicology Res. Lab., Health and Environmental Res., Dow Chemical Co., Midland, MI, 48640); Watanabe, P. G.; Gehring, P. J. *Environ Health Perspect* 21: 99-105; 1977.

The effects of inhaled vinylidene chloride (VDC; 1,1-dichloroethylene) were determined in rats and mice. In maleSprague-Dawley fasted and fed rats exposed to either 10 or 200 ppm VDC for 6 hr, fasting augmented the process whereby reactive intermediates formed from VDC induced tissue damage. Rats exposed to 200 ppm labeled VDC exhaled a greater percentage of their acquired body burden of radioactivity as unchanged VDC than did animals exposed to 10 ppm. However, rats exposed to the higher concentration showed a greater percentage of body burden remaining in the carcass at 72 hr after exposure. Retention of radioactivity in the carcass was greater in fasted rats exposed to 200 ppm VDC, despite a smaller fraction of the body burden biotransformed by fasted rats. The presence of mercapturic acid derivatives in the urine of exposed rats indicated a major role for glutathione in the detoxification of VDC. Apparently, VDC metabolism represents a balance between biotransformation pathways leading to detoxification by way of glutathione or to covalent binding to tissue nucleophiles and subsequent tissue damage. Enhanced susceptibility to VDC was noted in Ha(ICR) mice exposed to 10 ppm VDC for 6 hr, probably because of their more rapid metabolism of VDC and greater production of alkylating VDC metabolites over that in the rat. (9 refs)

78-3817 **Effect of Various Treatments on Toxicity of Inhaled Vinylidene Chloride.** (Eng) Short, R. D. (Pharmacology and Toxicology, Midwest Res. Inst., Kansas City, MO, 64110); Winston, J. M.; Minor, J. L.; Seifter, J.; Lee, C. C. *Environ Health Perspect* 21: 125-129; 1977.

The acute toxicity of continuously inhaled vinylidene chloride (VDC) was investigated in CD-1 mice and CD rats, and the effects of various treatments on this toxicity were determined. The animals were exposed to varying VDC concentrations for 22-23 hr/day. VDC was more lethal and more hepatotoxic mice than male rats. Furthermore, male mice were more sensitive to the lethal effects of VDC than females; the respective concentrations causing 50% mortality were 98 and 105 ppm. The effects of disulfiram, diethyldithiocarbamate, thiram, cysteine, methionine, N-acetylcysteine, SKF 525-A, cobaltous chloride, dimercaprol, phenoxybenzamine, propranolol, vitamin C, and DL-α-tocopherol acetate on VDC toxicity were evaluated. Disulfiram, diethyldithiocarbamate and thiram reduced the acute lethal and hepatoxic effects of inhaled VDC. Disulfiram also reduced the levels of covalently bound radioactivity in the liver and kidney following ip administration of ^{14}C-VDC. It is suggested that disulfiram and its metabolites act by not only reducing the activation of VDC, but also by increasing the extent of detoxification. (25 refs)

78-3818 **Damage to Hepatic Cellular Membranes by Chlorinated Olefins with Emphasis on Synergism and Antagonism.** (Eng) Reynolds, E. S. (Dept. Pathology, Univ. Texas Medical Branch, Galveston, TX, 77550, 77550); Moslen, M. T. *Environ Health Perspect* 21: 137-147; 1978.

The biochemical mechanisms responsible for the toxicity of vinyl chloride (VC), 1,1-dichloroethylene (1,1-DCE), trichloroethylene (TCE), and perchloroethylene (PCE) were investigated in male Sprague-Dawley rats pretreated with phenobarbital, 3-methylcholanthrene, hexachlorobenzene, spironolactone, or pregnenolone-16α-carbonitrile. The most nonsymmetrically depolarized compound, 1,1-DCE, was the most hepatotoxic and caused a unique pattern of hepatocellular injury involving mitochondria, plasma membranes, and chromatin. The injury induced by the other chloroethylenes appeared to affect the structural integrity of the endoplasmic reticulum profoundly, with the toxic potential in the following order: TCE > VC > PCE. Pretreatments that increased the cytochrome P-450 content (increased metabolic activation) enhanced or were synergistic to the hepatotoxic potential of TCE, VC, and PCE, but they were protective or antagonistic to 1,1-DCE hepatotoxicity. This suggests that the biologic response to 1,1-DCE may be expressed by a different metabolic pathway. Glutathione appears to be involved in the biologic response to all nonsymmetric chloroethylenes and to act as an antagonist against injury. Marked differences in the patterns of injury and the biologic responses suggest that more than one mechanism is involved in the production of injury by chloroethylenes. (37 refs)

78-3819 **Gas-Liquid Chromatographic Determination of Trichloroethylene Metabolites in Urine.** (Eng) Nomiyama, H. (Dept. Environmental Health, Jichi Medical Sch., Minamikawachi-machi, Tochigi-ken 329-04, Japan); Nomiyama, K.; Uchiki, H. *Am Ind Hyg Assoc J* 39(6): 506-510; 1978.

A gas-liquid chromatography technique using an electron capture detector was developed to determine all the urinary metabolites of trichloroethylene (TCE) on a single column. With urine from TCE-exposed rats, detection limits were as low as 0.1-5 nanograms. (10 refs)

78-3820 **Chemical Structure, Reactivity, and Carcinogenicity of Halohydrocarbons.** (Eng) Van Duuren, B. L. (Lab. of Organic Chemistry and Carcinogenesis, Inst. of Environmental Medicine, New York Univ. Medical Center, New York, NY, 10016). *Environ Health Perspect* 21: 17-23; 1977.

The structural and carcinogenic properties of halohydrocarbons are reviewed, with particular emphasis on trichloroethylene (TCE). Based on studies of the chemical structure, reactivity, and possible metabolic pathways of TCE, the compound was predicted to be carcinogenic, particularly to the liver. These studies also suggested that TCE is metabolized to an epoxide and that this epoxide may be the activated carcinogenic intermediate of TCE in liver carcinogenesis. The binding of TCE to liver microsomal proteins of male B6C3F1 hybrid mice, which are susceptible to TCE-induced liver tumorigenesis, was found to be significantly higher than the binding of TCE to microsomal proteins of male Osborne-Mendel rats, which are resistant to TCE-induced hepatocellular carcinoma. Also, the in vitro binding of TCE to liver microsomal proteins was higher for male than female B6C3F1 mice; females have been reported to show a lower incidence of TCE-induced hepatocellular carcinoma than males. The results of carcinogenicity assays of vinyl bromide and polyvinyl bromide are also given. Neither compound appeared to be carcinogenic when injected sc or when applied to the skin of mice. The carcinogenicity of other chlorinated hydrocarbons that are widely used in the chemical industry and that are structurally analogous to TCE and vinyl chloride is discussed briefly. (43 refs)

78-3821 **Biochemical and Toxicological Effects of Combined Exposure to 1,1,1-Trichloroethane and Trichloroethylene on Rat Liver and Brain.** (Eng) Vainio, H. (Dept. Industrial Hygiene and Toxicology, Inst. Occupational Health, Haartmaninkatu 1, SF-00290 Helsinki 29, Finland); Savolainen, H.; Pfaffli, P. *Xenobiotica* 8(3): 191-196; 1978.

Male Wistar rats inhaled a mixture of 1,1,1-trichloroethane (1,1,1-TCE) (500 ppm) and trichloroethylene (200 ppm) 6 hr/day for 4 days. As a result, 1,1,1-TCE accumulated in the perirenal fat, the hepatic RNA content doubled, hepatic glutathione concentrations decreased slightly, and uridine diphosphate-glucuronosyl transferase activity doubled. A 5-day exposure increased the content of both solvents in various organs rapidly, depressed brain RNA, and decreased in styrene monooxygenase activity. Changes noted on day 5 had also occurred on days 1-4 but had reverted during each postexposure period. (22 refs)

78-3822 **Metabolism and Mutagenicity of Halogenated Olefins--A Comparison of Structure and Activity.** (Eng) Henschler, D. (Institut fur Toxikologie und Pharmakologie, Universitat Wurzburg, D-8700 Wurzburg, W. Germany). *Environ Health Perspect* 21: 61-64; 1977.

The metabolism of various halogenated olefins was studied in vivo, and their mutagenicity was investigated in vitro in a modified Ames testing system. The results of the mutagenicity test were compared with in vivo carcinogenicity findings reported previously. In mammals, chlorinated ethylenes are first metabolized to epoxides, which may then undergo intramolecular rearrangement. This reaction has been studied in the entire series of chlorinated epoxyethanes. The rearrangement products found were acyl chlorides (tetrachloro-, trichloro-, and 1,1-dichloroethylenes) or chlorinated aldehydes (cis- and trans-1,2-dichloroethylene, vinyl chloride). In vivo experiments yielded products that were further derivatives of these rearrangement products, except that with trichloroethylene, the only rearrangement product was chloral. Tetrachloroethylene, trichloroethylene, cis-1,2-dichloroethylene, trans-1,2-dichloroethylene, 1,1-dichloroethylene, and vinyl chloride were then tested for mutagenicity in the *Salmonella typhimurium* assay. Vinyl chloride, trichloroethylene, and 1,1-dichloroethylene were mutagenic, suggesting that asymmetric chlorine substitution renders the epoxides unstable and mutagenic. High electrophilicity may be a prerequisite for the mutagenic and carcinogenic activity of these chlorinated ethylenes. (20 refs)

78-3823 **Mutagenicity of the Halogenated Olefin, 2-Bromo-2-chloro-1,1-difluoroethylene, a Presumed Metabolite of the Inhalation Anesthetic Halothane.** (Eng) Garro, A. J. (Dept. Microbiology, Mount Sinai Sch. Medicine, City Univ. New York, New York, NY, 10029); Phillips, R. A. *Environ Health Perspect* 21: 65-69; 1977.

The mutagenicity of 2-bromo-2-chloro-1,1-difluoroethylene (BCD), a metabolite of the anesthetic halothane, was investigated in *Salmonella typhimurium* and *Bacillus subtilis*. BCD induced base and frameshift mutations in *S. typhimurium*. With *B. subtilis*, an increase in the number of mutants and inactivation of transforming activity were noted. The significance of these findings with respect to morbidity in anesthesia personnel is not known. (26 refs)

78-3824 **Formation of N-Nitrosamines in Cutting Fluids.** (Eng) Rappe, C. (Dept. Organic Chemistry, Univ. Umea, Umea, Sweden); Zingmark, P. A. *IARC Sci Publ* (19): 213-217; 1978.

Two grinding fluid concentrates containing triethanolamine, nitrite, and water were analyzed for N-nitrosodiethanolamine after storage for 5-7 mo. Between 400 and 800 ppm N-nitrosamine were formed, even though the pH values of the fluids were 10.2-11.4. These analyses clearly show that the mixing of nitrite and an amine in a technical product should always be regarded with suspicion concerning

N-nitrosamine formation, especially if the product is stored. (6 refs)

78-3825 **Mutagenicity Screening of Industrial Chemicals: Seven Aliphatic Amines and One Amide Tested in the Salmonella/Microsomal Assay (Meeting Abstract).** (Eng) Hedenstedt, A. (Environmental Toxicology Unit, Wallenberg Lab., Univ. Stockholm, Lilla Frescati, 104 05 Stockholm 50, Sweden). *Mutat Res* 53(2): 198-199; 1978. (no refs)

78-3826 **Genetic Activity of Allyl Chloride.** (Eng) McCoy, E. C. (Dept. Microbiology, New York Medical Coll., Valhalla, NY, 10595); Burrows, L.; Rosenkranz, H. S. *Mutat Res* 57(1): 11-15; 1978.

The mutagenic activity of allyl chloride (3-chloroprene) for *Salmonella typhimurium* TA100 and TA1535, but not TA1538, was demonstrated using an assay procedure that protected against evaporation of the volatile test substance. Allyl chloride also induced gene conversions in *Saccharomyces cerevisiae* and displayed DNA-modifying activity for *Escherichia coli*. These results are in contrast to a recent study that reported that allyl chloride was devoid of genetic activity for *S. typhimurium*, and they indicate that the volatility of the test agent is an important factor that must be taken into consideration. (30 refs)

78-3827 **Potential Mutagenic and Adverse Male Reproductive Effects of 1,2,3,4-Tetrabromobutane: A Dominant Lethal Study in the Rat.** (Eng) Simon, G. S. (Div. Toxicology, Dept. Pharmacology, Medical Coll. Virginia, Virginia Commonwealth Univ., Richmond, VA, 23298); Tardiff, R. G.; Borzelleca, J. F. *Toxicol Appl Pharmacol* 44(3): 661-664; 1978.

The results of a dominant lethal assay in which 1,2,3,4-tetrabromobutane (TBB) was given po to Sprague-Dawley rats (10 or 40 mg/kg/day x 10) are summarized. Statistically significant adverse effects that were not dose-related were induced by both doses of TBB during weeks 6-13. The data suggest that TBB is not a potent mutagen but that it may affect male reproductive function and performance adversely. (3 refs)

78-3830 **Chromosome Investigations of Persons Exposed to Dimethylcarbamoyl Chloride and Diethylcarbamoyl Chloride (Meeting Abstract).** (Eng) Fleig, I. (Arbeitsmedizin und Gesundheitsschutz, BASF, Aktiengesellschaft, 6700 Ludwigshafen, W. Germany); Thiess, A. M. *Mutat Res* 53(2): 188; 1978. (no refs)

78-3831 **Effect of Reovirus Infection on Pulmonary Tumor Response to Urethan in Strain A Mice.** (Eng) Theiss, J. C. (Dept. Community Medicine, M-014, Sch. Medicine, Univ. California at San Diego, La Jolla, CA, 92093); Stoner, G. D.; Kniazeff, A. J. *J Natl Cancer Inst* 61(1): 131-134; 1978.

The effect of reovirus type 3 infection on the pulmonary adenoma response to urethan in strain A mice was examined. Mice were given low (0.25 mg/g), medium (0.5 mg/g), or high (1.0 mg/g) doses of urethan and exposed to reovirus either 6 days before, on the same day as, or 14 days after urethan administration. At all doses of urethan and at all times of reovirus exposure, the lung tumor response was significantly (30%-60%) less than the response obtained with urethan alone. In another experiment, mice were given 1.0 mg/g urethan and exposed to reovirus four times: 7 days before, on the same day as, 7 days after, and 14 days after urethan administration. Multiple exposure to reovirus enhanced the pulmonary adenoma response to urethan. A single exposure of strain A mice to reovirus may increase the capacity of the immune system by a rebound effect, thus suppressing lung tumor formation in response to urethan, whereas multiple exposure causes a continued suppression of the immune system, resulting in an enhancement of the pulmonary adenoma response to urethan. Virus infection may be important in the carcinogenic response of humans to environmental chemicals. (26 refs)

78-3832 **Carcinogenic Effects of Niridazole in Rats.** (Eng) Bulay, O. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, 42nd and Dewey Ave., Omaha, NB, 68105); Clayson, D. B.; Shubik, P. *Cancer Lett* 4(6): 305-310; 1978.

The carcinogenicity of the drug niridazole [NR: 1-(5-nitro-2-thiazolyl)-2-imidazolidinone]was studied in MRC rats. The rats were chronically fed levels of 0.1%, 0.05%, 0.025%, and 0% NR in the diet for 50-140 wk. Mean life-spans were 47, 70, 80, and 102 wk, respectively. Treated females lived an av of 20 wk longer than treated males. NR primarily induced kidney and forestomach tumors. Kidney tumors developed in a higher percentage of males than females, and they were dose-dependent for those sexes. Histologically, the kidney tumors were primarily tubular, solid, and papillary adenomas; adenocarcinomas; and mesenchymal tumors. Controls did not develop kidney tumors. The stomach tumors were all papillomas. Their induction was also dose-dependent, and no major difference was observed between males and females. At the lowest concentration, stomach tumor incidence in controls and in treated animals was similar. Tumor latency was shortest (21 wk) in males treated with the highest dose. (15 refs)

78-3833 **Report on Bioassay of 2-Amino-5-nitrothiazole for Possible Carcinogenicity.** (Eng) Fredrickson, D. S. (NIH, Bethesda, MD, 20014). *Fed Register* 43(143): 32191; 1978.

2-Amino-5-nitrothiazole (ANT) was administered to Fischer 344 rats (300 or 600 ppm diet for 100 wk) and B6C3F1 mice (50 or 100 ppm diet for 104 wk), and tumor formation was monitored. Tumors of the hematopoietic system (lymphomas, granulocytic leukemia) occurred in male rats, but the compound was not carcinogenic in female rats and in the mice. (no refs)

78-3834 **Comparison Between Radiation and Chemicals in the Time of Formation of Chromosome Aberrations Induced in Male Germ Cells of Mice (Meeting Abstract).** (Eng) Generoso, W. M. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN); Cain, K. T.; Huff, S. W.; Krishna, M. *Mutat Res* 53(2): 191; 1978. (no refs)

78-3835 **High Incidence of Hepatic Tumours in Rats Fed Mouldy Rice Contaminated with *Aspergillus versicolor* Containing Sterigmatocystin.** (Eng) Ohtsubo, K. (Dept. Carcinogenesis and Cancer Susceptibility, Inst. Medical Science, Univ. Tokyo, Shirokanedai, Minato-ku, Tokyo 108, Japan); Saito, M.; Kimura, H.; Tsuruta, O. *Food Cosmet Toxicol* 16(2): 143-149; 1978.

The hepatocarcinogenicity of rice contaminated with *Aspergillis versicolor*, a mold that produces the mycotoxin sterigmatocystin (SMC), was investigated in feeding trials with male Donryu rats. A strain of *A. versicolor* isolated from soya beans was injected into minimally polished rice, cultured, pelleted, and mixed with a basal diet. Three groups of 20 rats each were fed a diet containing 0, 5, or 10 ppm SMC for up to 709 days, when all survivors were killed. The doses of SMC were equivalent to a daily intake of 75 or 150 μg/rat, the lowest levels ever investigated. Of the 13 rats in each test group that died between day 465 (when the first animal with a tumor died) and day 709, 12 of those fed 10 ppm SMC and 11 fed 5 ppm developed hepatic tumors, mostly hepatocellular carcinomas. Three hemangiosarcomas were also observed. All of the tumor bearers had hyperplastic nodes and areas, and one-fourth had multiple pulmonary metastases. Non-tumor-bearing SMC-treated animals that died between days 209 and 435 had areas of hyperplasia only or hyperplastic areas and nodes. It is concluded that SMC is a more potent carcinogen than was previously thought, having nearly the same degree of carcinogenicity as aflatoxin B_1. (27 refs)

78-3836 **Sex and Age Differences in Luteoskyrin Hepatotoxicity.** (Eng) Ueno, I. (Inst. Medical Sciences, Univ. Tokyo, Shirogane-Dai, Minato-ku, Tokyo, Japan). *Ann Nutr Aliment* 31(4/5/6): 789-802; 1977.

Experiments correlating luteoskyrin (LS) accumulation in mouse liver with its toxicity are reported. LS, a hepatotoxic and hepatocarcinogenic mycotoxin from the fungus of yellowed rice (*Penicillium islandicum* Sopp), showed different toxicities depending on the age and sex of the mice. The LD_{50} of sc administered LS was lowest in newborn mice (7.2 mg/kg for males and 6.3 mg/kg for females), and it increased with age to 154 mg/kg for the male and 2 g/kg for the female. When 7.1 μg/g of radiolabeled LS was injected sc into suckling (2-wk-old) and adult (10-wk-old) mice, the radioactivity in the livers of suckling mice was several times higher than that in adult livers. When 0.43 mg of radiolabeled LS was given po to mice of both sexes, the percentage of radioactivity in the liver was higher in male than in female mice (more than double 23 hr after administration). This was also the case when a high dose of 2.52 mg was given po. In all mice, the specific radioactivity of the mitochondria was highest among the subcellular fractions of the liver. LS injected iv was excreted via the feces more rapidly in female than in male mice. These results showed that LS accumulated in the livers of suckling or male mice in larger amounts than in livers of adult or female mice and that this difference in accumulation was correlated with hepatotoxicity. The sex difference in the accumulation of LS in mouse liver is due to the different capacities of biliary excretion of this mycotoxin between the two sexes. A previous long-term feeding experiment demonstrated that the hepatocarcinogenicity of LS was higher in male than in female mice; therefore, the sex difference in the biliary excretion of LS may also have influenced its hepatocarcinogenicity. (34 refs)

78-3837 **Specific and Non-Specific Interactions of Two Carcinogenic Mycotoxins, Luteoskyrin and Rugulosin with Nucleic Acids.** (Eng) Bouhet, J. C. (Service de Biochimie, C.E.N. Saclay, B.P. n.2, 91190, Gif-sur-Yvette, France); Van Chuong, P. P. *Ann Nutr Aliment* 31(4/5/6): 811-830; 1977.

Specific and nonspecific interactions of the stereoisomeric and carcinogenic anthraquinonelike pigments luteoskyrin and rugulosin with nucleic acids are reported. Studies were performed with binary polychelates (pigment-metal) and ternary complexes (pigment-metal-nucleic acids). An unspecific complex with double-stranded polynucleotides resulted from simple adsorption of the polychelate onto the double helix of DNA, whereas a complex specific for single-stranded DNA (or polypurine nucleotides) resulted from the electrostatic association of separate pigment-metal units with the polyphosphate chain. Additional stabilization was obtained by hydrophobic interaction between stacked aromatic moieties of pigment and purine units. A model of interaction is proposed for both of the complexes. (26 refs)

78-3838 **Long-Term Testing of Patulin Administered Orally to Sprague-Dawley Rats and Swiss Mice.** (Eng) Osswald, H. (Institut fur Toxikologie und Chemotherapie, Deutsches Krebsforschungszentrum, Heidelberg, W. Germany); Frank, H. K.; Komitowski, D.; Winter, H. *Food Cosmet Toxicol* 16(3): 243-247; 1978.

Administration of patulin to female Sprague-Dawley rats for 64 wk and to pregnant Swiss mice on gestation days 14-19 did not produce a carcinogenic effect in the rats or in the offspring of the mice. However, 11/51 female and 8/43 male neonates died, all showing similar signs of toxicity. (no refs)

78-3839 **Tumorigenic Effect of 1-Hydrazinophthalazine Hydrochloride in Mice.** (Eng) Toth, B. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, 42d St. and Dewey Ave., Omaha, NB, 68105). *J Natl Cancer Inst* 61(5): 1363-1365; 1978.

The toxicity and carcinogenicity of 1-hydrazinophthalazine hydrochloride (HPH), a widely used hypertensive drug, were studied in Swiss albino mice. In the toxicity study, the mice were given five dose levels (wt/volume) of HPH (1%, 0.5%, 0.25%, 0.125%, and 0.0625%) in the drinking water for 35 days. On the basis of survival rates, body wt, chemical consumption levels, and histological changes, the 0.125% dose was found suitable for lifelong treatment. This dose in drinking water was then given to 100 6-wk-old mice over their life-spans. Av daily consumption of HPH was 5.4 mg for the females and 7.4 mg for the males. All animals were checked and weighed at weekly intervals, and the gross pathology was noted. Treated animals were allowed to die or were killed when found in poor condition; a sex-matched control was also killed. Thirty treated females developed 81 lung tumors (adenomas and adenocarcinomas) and 23 treated males developed 58 lung tumors. Of the untreated mice, 18 females developed 20 lung tumors and 13 males developed 16. Av age at death was 78 wk for treated females, 79 wk for treated males, 78 wk for untreated females, and 75 wk for untreated males. A few other types of tumors, such as malignant lymphomas and angiosarcomas of the liver, were found in the treate mice, but their incidence was not considered significant. (2 refs)

78-3840 **Detection of Mutagenicity of the Colon Car cinogen 1,2-Dimethylhydrazine by the Host-me diated Assay and its Correlation to Carcinogenicity.** (Eng Moriya, M. (Toxicology Div., Inst. Environmental Toxicology, Suzuki-cho 2-772, Kodaira-shi, Tokyo 187, Japan); Kato, K.; Ohta, T.; Watanabe, K.; Watanabe, Y.; Shirasu, Y. *J Nat Cancer Inst* 61(2): 457-460; 1978.

The mutagenicity of 1,2-dimethylhydrazine (DMH) was evaluated by a host-mediated assay in outbred ICR male mice, using *Salmonella typhimurium* G46 as the tester strain. The mice were given 2 ml G46 ip (2.2 x 10^8 cells/ml) followed immediately by DMH po (4.5, 11.25, 22.5, 33.75, or 45 mg/kg). A strong dose-response relationship was demonstrated in mutation induction by DMH. At 45 mg/kg, the mutation frequency was 900 times the control levels. Pretreatment of the mice for 8 days with disulfiram (DSF: 5-2 mg/kg/day po) markedly reduced the mutagenicity of DMH. At 20 mg/kg/day, mutation induction by 45 mg/kg DMH was reduced to 4% of the control value. The effects of mouse strain and sex on these results were also tested. Mutation induction was significantly lower in C57BL/6 mice than in ICR mice of either sex, and male mice showed a higher mutation rate than the females of each strain. (22 refs)

78-3841 **Inhibition of Testicular DNA Synthesis by Chemical Mutagens and Carcinogens as a Valid Mammalian Short-Term Testing Procedure (Meeting Abstract).** (Eng) Seiler, J. P. (Swiss Federal Res. Station, CH-8820 Waedenswil, Switzerland). *Mutat Res* 53(2): 260; 1978. (1 ref)

78-3842 **A Double-Blind Study on the Effect of Purified Cellulose Dietary Fiber on 1,2-Dimethylhydrazine-induced Rat Colonic Neoplasia.** (Eng) Freeman, H. J. (Gastrointestinal Res. Lab., Veteran's Admin. Hosp., 415 Clement St., San Francisco, CA, 94121); Spiller, G. A.; Kim, Y. S. *Cancer Res* 38(9): 2912-2917; 1978.

The incidence, distribution, size, and histopathology of grossly visible colonic tumors induced by parenteral administration of 1,2-dimethylhydrazine (DMH) were examined in 6-wk-old male Wistar rats. The rats were fed either a chemically defined fiber-free diet or a nutritionally and calorically equivalent diet containing a purified fiber component, microcrystalline cellulose. Twenty rats of each diet group were inoculated sc with DMH (25 mg/kg/wk x 16). Cellulose ingestion reduced the number of animals with colonic tumors and the total number of tumors. This protective effect of cel lulose appeared to be time-dependent and associated with a shift in tumor distribution from the proximal colon to a more distal site. Cellulose fiber had no apparent effect on colonic tumor size, histopathology, or the incidence of other tumors known to occur in this experimental animal model. This study strongly supports the hypothesis that fiber is an important protective agent against colonic neoplasia development. Although the mechanism for this protective effect remains obscure, it appears to be temporally related to the duration of fiber ingestion as well as to a differential fiber effect on either the luminal content or the mucosa of the proximal and distal colon. (27 refs)

78-3843 **Colonic Protection from Dimethylhydrazine by a High Fiber Diet.** (Eng) Chen, W. F. (Quakertown, PA); Patchefsky, A. S.; Goldsmith, H. S. *Surg Gynecol Obstet* 147(4): 503-506; 1978.

Protection from the carcinogenic effects of 1,2-dimethylhydrazine (DMH) on the colon afforded by a diet high in fiber bran was studied in female CF1 mice. Two groups of mice were fed diets that were identical except that wheat bran composed 40% by wt of one diet. After 1 wk on the diets, all mice were injected sc on their backs with 20 mg/kg DMH. This dose was repeated on a weekly basis for 26 wk or until the mouse died. Histological studies were made of the colons of all animals that died between weeks 15 and 26 and all animals sacrificed at the end of 26 wk. Of the 400 mice in the study, 122 in the experimental group and 141 in the controls died during the first 15 wk, leaving 78 and 59 evaluable mice. The incidence of major pathological changes (atypical adenoma, invasive and in situ carcinoma) was much higher ($p < 0.02$) in the controls than in animals fed fiber bran. Adenomas that were not considered major pathology were much more frequent in control mice than in experimental mice. The investigation supports the claim that addition of bran to the diet has the ability to lower the incidence of carcinoma of the large intestine. (4 refs)

78-3844 **Kinetics of Changes in the Crypts of the Jejunal Mucosa of Dimethylhydrazine-treated Rats.** (Eng) Sunter, J. P. (Dept. Pathology, Royal Victoria Infirmary, Queen Victoria Road, Newcastle upon Tyne NE1 4LP, England); Appleton, D. R.; Wright, N. A.; Watson, A. J. *Br J Cancer* 37(5): 662-672; 1978.

The effects of sc administration 1,2-dimethylhydrazine (DMH: 15 mg/kg/wk) on the crypts of the jejunal mucosa were studied in female Wistar rats. In animals killed after 21-27 wk of DMH treatment, the incidence of colonic and small-intestinal neoplasms was 100% and 37%, respectively. The large-bowel tumors were generally multiple, whereas the small-intestinal tumors were frequently solitary. Most of the small intestinal tumors (33/39) were situated in the most proximal part of the jejunum or in the distal duodenum. A striking elongation of the intestinal crypts was seen after 24 wk or more of DMH treatment. This hyperplasia was generalized, and it occurred in the absence of any features of atypia in both tumor-bearing and non-tumor-bearing animals. In the hyperplastic jejunal crypts, the absolute size of the proliferative compartment was increased, but the growth fraction calculated from labeling studies appeared to fall, probably because of a reduction in the relative size of the proliferating population in this compartment. No convincing alteration in actual cell-cycle time was observed in the abnormal crypts, but there was a 25% increase in the cell production rate. (28 refs.)

78-3845 **A Requirement of Pi for the Transitory Uncoupling of Rat Liver Mitochondria by Hydrazine, When β-Hydroxybutyrate Is the Substrate.** (Eng) Hadler, H. I. (Dept. Chemistry and Biochemistry, Southern Illinois Univ., Carbondale, IL, 62901); Cook, G. L. *J Environ Pathol Toxicol* 1(4): 419-432; 1978.

The mitochondrial target of hydrazine (HZ) was studied using rat liver mitochondria. HZ combined with inorganic phosphate (Pi) had a transitory stimulatory effect on mitochondrial respiration (transitory uncoupling), although neither compound alone had this effect. HZ also prevented the subsequent addition of ADP from establishing coupled phosphorylation. Both effects of HZ were eliminated by the addition of ADP or ATP before HZ or during the induction period associated with HZ. The transitory uncoupling effect was also prevented by pyrophosphate, magnesium ion, antimycin or rutamycin when they were added before HZ. Aurovertin delayed but did not block the uncoupling effect. The transitory uncoupling induced by HZ and Pi appeared to be restricted to conditions in which β-hydroxybutyrate was the substrate. In a mitochondrial system that included ATP, gramicidin, potassium ion, and sulfate, HZ, acting as a large cation but not as a nucleophile, blocked the swelling and the increment in ATPase activity associated with potassium ion. The data suggest that when β-hydroxybutyric acid is the substrate, an electrophilic form of Pi is the mitochondrial target of HZ. The data support an experimental confluence between oxidative phosphorylation and chemical carcinogenesis, and they explain the previously observed toxic effect of HZ on mitochondria. (34 refs)

78-3848 **A Cell-free Assay Measuring Repair DNA Synthesis in Human Fibroblasts.** (Eng) Ciarrocchi, G. (Laboratorio di Genetica Biochimica ed Evoluzionistica, Consiglio Nazionale delle Ricerche, 27100 Pavia, Italy); Linn, S. *Proc Natl Acad Sci USA* 75(4): 1887-1891; 1978.

DNA repair synthesis was measured by a cell-free assay that involves osmotic disruption of confluent cultured human fibroblasts that have been irradiated or exposed to chemical carcinogens. Deoxythymidine triphosphate was used as a precursor. Fibroblasts from various xeroderma pigmentosum (XP) cell lines showed the deficiencies of UV-induced DNA synthesis predicted from in vivo studies, but they gave normal responses to methyl methanesulfonate. Dose responses and levels of repair synthesis (relative to UV stimulation) induced by x-radiation, 4-nitroquinoline 1-oxide, and N-acetoxy-2-acetylaminofluorene were comparable to those seen with intact cells by autoradiography. However, the level of synthesis induced by methyl methanesulfonate was much greater, comparable to that obtained with UV radiation . A pyrimidine dimer-specific enzyme, phage T4 endonuclease V, stimulated the rate of UV-induced repair synthesis with normal and XP cell lines. A number of applications are suggested for this assay system: (1) to identify agents that induce DNA repair and the cells that respond abnormally to such induction; (2) as an in vitro complementation assay using repair-defective cells and proteins obtained from repair-proficient cells; and (3) to measure DNA replication in vitro by using actively growing fibroblasts and thymidine in the system. 78-3849 **DNA Repair Synthesis in Rat Retinal Ganglion Cells Treated with Chemical Carcinogens or Ultraviolet Light In Vitro, with Special Reference to Aging and Repair Level.** (Eng) Ishikawa, T. (Dept. Experimental Pathology, Cancer Inst., 1-37-1, Kamiikebukuro, Toshima-ku, Tokyo 170, Japan); Takayama, S.; Kitagawa, T. *J Natl Cancer Inst* 61(4): 1101-1105; 1978.

A system in which the retinal tissues of noninbred Wistar rats were used in combination with autoradiography was developed for measuring of DNA repair synthesis in ganglion cells of the CNS. Retinal tissues in short-term organ culture were treated with 4-nitroquinoline 1-oxide (0.032-3.2 x 10^{-5} M), ethylnitrosourea (0.032-3.2 x 10^{-3} M), or methylmethanesulfonic acid (0.032-3.2 x 10^{-3} M) plus tritiated thymidine, or they were irradiated with UV light (60, 190, 1,900 or 6,000 ergs/mm^2) and then treated with tritiated thymidine. In carcinogen-treated groups, unscheduled DNA synthesis was clearly demonstrated as silver grains over the nuclei of cells in the outer nuclear layer of the retina. The cells in this layer had uniform numbers of grains. A preliminary study revealed that aging had no effect on the levels of DNA repair in retinal ganglion cells. (27 refs)

78-3856 **Alkylation of Deoxyribonucleic Acid by Carcinogens Dimethyl Sulphate, Ethyl Methanesul-**

phonate, N-Ethyl-N-nitrosourea and N-Methyl-N-nitrosourea. Relative Reactivity of the Phosphodiester Site Thymidylyl(3′-5′)thymidine. (Eng) Swenson, D. H. (Natl. Center Toxicological Res., Jefferson, AR, 72079); Lawley, P. D. *Biochem J* 171(3): 575-587; 1978.

Determination was made of the extent of alkylation of the phosphodiester sites of DNA by four carcinogens: dimethyl sulfate (DS), ethyl methanesulfonate, N-methyl -N-nitrosourea, and N-ethyl -N- nitrosourea (ENU). As a first step, the ethyl phosphotriester of thymidyl(3′-5′)thymidine [dTp(Et)dt] was isolated and characterized as a product of the ethylation of DNA by ENU, by procedures similar to those reported previously for the methyl homolog. Enzymic degradation to yield alkyl phosphotriesters from DNA alkylated by these carcinogens was studied quantitatively, and the relative yields of the triesters dTp(Alk)dT were determined. The relative reactivity of the phosphodiester group dTpdT to each of the carcinogens was obtained and compared with that of overall DNA or with that of the N-7 atom of guanine in DNA. Relative reactivity of the phosphodiester group was lowest toward DS, the least electrophilic of the reagents used, and highest toward ENU the most electrophilic-reagent. The nature of the alkyl group transferred also influenced the reactivity of the phosphodiester site, since this site was relatively more reactive toward ethylation than would be predicted simply from the known Swain-Scott s values of the alkylating agents. It was therefore suggested that the steric accessibility of the weakly nucleophilic phosphodiester group on the outside of the DNA macromolecule favors its reaction with ethylating, as opposed to methylating, reagents. The nucleophilicity of overall DNA was less than that of the N-7 atom of guanine in DNA. The reactivity of overall DNA was markedly high toward the alkylnitrosourea, despite their relatively low s values. This was ascribed to an electrostatic factor that favored reaction of the negatively charged polymer with alkyldiazonium cation intermediates. (26 refs)

78-3858 **Induction of Colon Tumors in 1,2-Dimethylhydrazine-resistant Lobund Wistar Rats by Methylazoxymethanol Acetate.** (Eng) Pollard, M. (Lobund Lab., Univ. Notre Dame, Notre Dame, IN, 46556); Zedeck, M. S. *J Natl Cancer Inst* 61(2): 493-494; 1978.

Differences in the susceptibility of Sprague-Dawley (S-D: high) and Lobund Wistar (LW: low) rats to 1,2-dimethylhydrazine (DMH) were studied by determining tumor incidence in both strains upon treatment with the product of DMH metabolism, methylazoxymethanol (MAM). Rats were inoculated sc with 30 mg/kg/wk MAM acetate for 10 wk. Although 7/7 LW rats and 10/10 S-D rats developed intestinal tract tumors, the tumor incidence was much greater in S-D rats. They developed 20.4 tumors/animal, most of which were adenocarcinomas extending through the muscularis and into the serous membrane covering the intestine. LW rats averaged 3.1 tumors/animal, and they were generally smaller in size and less invasive. The livers of all animals were damaged, with cirrhotic changes being seen in LW rats. Assays of NAD+-dependent dehydrogenase activity in colon tissue indicated that LW rats indicate that the differential susceptibility of these two rat stocks to colon tumor induction is partially related to metabolic activation of DMH and to other, as yet undetermined, endogenous factors. (11 refs)

78-3859 **Effect of Colostomy on Intestinal Carcinogenesis by Methylazoxymethanol Acetate in Rats.** (Eng) Matsubara, N. (Dept. Surgery, Gifu Univ. Sch. Medicine, Gifu City 500, Japan); Mori, H.; Hirono, I. *J Natl Cancer Inst* 61(4): 1161-1164; 1978.

The effect of the fecal stream on the induction of intestinal tumors was studied in three groups of SD rats. Rats in Group 1 were subjected to single-barreled colostomies for the complete exclusion of the fecal stream at the proximal one-third level of the colon and were given consecutive iv injections of methylazoxymethanol acetate (MAMA). Rats in Group 2 were given MAMA alone. Rats in Group 3 were not treated and served as controls. Tumors were noted in the small and large intestines of almost all Group 1 and 2 rats. Only the multiplicity of the lesions in the entire intestinal tract and tumor incidence in the oral one-third of the colon were significantly higher in Group 2 (9.3, 72.2%) than in Group 1 (5.4, 28%). In spite of the single-barreled colostomies, 80% of the Group 1 animals developed tumors in the colon distal to the colostomy, where the mucosa did not have contact with the fecal stream. These results indicate that carcinogens can probably reach the intestinal mucosa via the vascular system as well as by biliary transport. (14 refs)

78-3867 **Metabolic Fate of the Precursors of N-Nitroso Compounds (III). Urinary Excretion of Nitrate in Man.** (Eng) Ishiwata, H. (Natl. Inst. Hygienic Sciences, 18-1 Kamiyoga 1-chome, Setagaya-ku, Tokyo, Japan); Mizushiro, H.; Tanimura, A.; Murata, T. *J Food Hyg Soc Jpn* 19(3): 318-322; 1978.

The amount of nitrate ingested in foods and beverages and the amount excreted in urine were determined in normal male and female volunteers. Urine specimens were collected three times from 11 random subjects on different days, and the mean nitrate concentration was 74.4 ppm. The amount of nitrate excreted in 24-hr urine samples from nine subjects who ingested a conventional diet containing 44.1-864.2 mg nitrate was 45.6-236.9 mg, which indicates that the urinary excretion of nitrate varies widely among individuals (27.4%-133.8%). No nitrate was detected in any urine specimens. Three subjects were fed a low-nitrate diet from day -1 to day 4. On days 0 and 2, subject A ingested 200 mg sodium nitrate and on day 0 subjects B and C ingested salted Chinese cabbage containing 75.1 mg nitrate at breakfast. In subject A, the urinary excretion of nitrate was not increased on the control days, but it was increased 78.3% and 86.2% on days 0 and 2. Almost the same excretion pattern was observed in subjects B and C. The amount of nitrate excreted increased by >25 mg every 2 hr on the experimental days in all three subjects. No nitrite was detected in any urine specimens, and neither nitrate nor nitrite was detected in any feces. (20 refs)

78-3868 **Alpha-Tocopherol: Uses in Preventing Nitrosamine Formation.** (Eng) Mergens, W. J. (Hoffmann-La Roche Inc., Nutley, NJ); Kann, J. J.; Newmark, H. L.; Fiddler, W.; Pensabene, J. *IARC Sci Publ* (19): 199-212; 1978.

The ability of the fat-soluble reducing agent α-tocopherol (TP, vitamin E) to destroy nitrite ion, thereby preventing nitrosamine formation, was evaluated in vitro, in vivo, in cigarettes, and in bacon. TP was emulsified in water and spray-dried to yield a free-flowing solid containing 33% by wt of TP. TP reacted with nitrosating agents in lipophilic and aqueous environments, and it destroyed nitrite in simulated gastric fluid. In rats, the elevation of serum glutamic pyruvic transaminase normally seen in animals treated with sodium nitrite [0.43 millimole (mmol)], and aminopyrene (0.15 mmol) was inhibited completely when TP (0.51 mmol) was included in the treatment. N-Nitrosodimethylamine (NDMA) yields were reduced by an av of 50% in cigarettes treated with 30 mg TP. Addition (via the cure soln) of TP to bacon inhibited N-nitrosopyrrolidine formation significantly after the bacon was fried and it also reduced the formation of NDMA, but to a lesser extent. Inhibition was greater with TP + sodium ascorbate than with the latter alone. The mechanism whereby TP reacts with a nitrosating intermediate is not fully understood. The data obtained in this study indicate that the reaction could take place completely within a lipid micelle. (24 refs)

78-3869 **Transnitrosation: An Important Aspect of the Chemistry of Aliphatic Nitrosamines.** (Eng) Singer, S. S. (NCI-Frederick Cancer Res. Center, Frederick, MD); Lijinski, W.; Singer, G. M. *IARC Sci Publ* (19): 175-181; 1978.

Investiations into the kinetics and mechanism of transnitrosation by aliphatic nitrosamines imply that a reactive intermediate (ie, thiocyanate ion), an Sn2-type displacement of the nitroso group, and a suitable receptor (urea, ammonia, or free amino acids) are required for the reaction. At pH 1.5-2, transnitrosation is rapid in the presence of thiocyanate ion, which is present in human saliva. The reaction could occur in the human stomach, where transnitrosating agents could form new carcinogenic nitrosamines by transfers to appropriate amines. (13 refs)

78-3870 **Problem of Artifacts in the Analysis of N-Nitroso Compounds.** (Eng) Krull, I. S. (Cancer Res. Div., Thermo Electron Corporation, 45 First Ave., Waltham, MA, 02154); Fan, T. Y.; Fine, D. H. *Anal Chem* 50(6): 698-701; 1978.

Various procedures that ensure the accuracy and precision of results obtained in the analysis of N-nitroso compounds are outlined. These techniques are designed to prevent both false-positive and false-negative findings during an analysis and to improve the reliability of N-nitroso analyses. Specific examples of the various types of causes of artifact formation are presented. (34 refs)

78-3871 **Salted Fish and Nasopharyngeal Carcinoma in Southern Chinese (Letter to Editor).** (Eng) Ho, J. H. (Medical and Health Dept., Inst. Radiology and Oncology, Queen Elizabeth Hosp., Kowloon, Hong Kong); Huang, D. P.; Fong, Y. Y. *Lancet* 2(8090): 626; 1978.

Extracts of salted fish and the urine of four pairs of albino rats fed salted fish, a staple food of the southern Chinese, produced dose-dependent mutagenicity in *Salmonella typhimurium* strains TA100 and TA98. Some of the mutagens in the fish may be N-nitroso compounds. These findings may explain the previously noted induction of carcinoma in rats fed salted fish and the high incidence of nasopharyngeal carcinoma in the southern Chinese. (14 refs)

78-3872 **Induction of Gastric Tumors in BD-VI Rats by Single Application of N-Methyl-N′-nitro-N-nitrosoguanidine in Dimethylsulfoxide (DMSO).** (Eng) Habs, M. (Inst. Toxicology and Chemotherapy, German Cancer Res. Center, Im Neuenheimer Feld 280, D-6900 Heidelberg, W. Germany); Deutsch-Wenzel, R.; Preussmann, R.; Schmahl, D. *Z Krebsforsch* 91(2): 183-188; 1978.

In an acute toxicity test, the LD_{50} of N-methyl-N′-nitro-N-nitrosoguanidine (MNNG) administered po to BD-VI rats in a 10% aqueous soln of dimethyl sulfoxide (DMSO) was 90 mg/kg. After a single po administration of 50 mg/kg (Group I), 75 mg/kg (Group II), or 100 mg/kg (Group III) of MNNG in a 10% aqueous soln of DMSO, generalized forestomach papillomatoses were found in all BD-VI rats after 500 days. Squamous cell carcinomas were detected in 7/24 rats in Group I, 12/26 in Group II, and 7/23 in Group III. Benign adenomatous dysplasia of the glandular stomach was diagnosed in 2 Group I rats, 1 Group II rats, and 12 Group III rats. Adenocarcinomas of the glandular stomach were induced in one animal of Groups I and II and in eight rats of Group III. From 20% to 30% of the MNNG-treated animals also showed degenerative cystic alterations in the liver with bile-duct proliferation. (25 refs)

78-3873 **The Influence of Ischemia and N-Methyl-N′-nitro-N-nitrosoguanidine on Rat Gastric Mucosa.** (Eng) Duris, I. (Dept. Internal Medicine, Medical Sch., Comenius Univ., Bratislava, Czechoslovakia); Popperova, E.; Zaviacic, M. *Tumor Res (Sapporo)* 12: 52-57; 1977.

The effect of ischemia on N-methyl-N′-nitro-N-nitrosoguanidine (MNNG)-induced carcinogenesis in the gastric mucosa of Dobra Voda (Czechoslovakia) strain male Wistar rats was determined. The rats were divided into five experimental groups: Group A underwent ligation of the gastric artery and, 8 wk later, received drinking water containing 83 mg MNNG for 8 wk; Group B received MNNG for 8 wk immediately after ligation of the gast artery; Group C received MNNG for 8 wk only; Group D underwent ligation of the gastric artery only; and Group E received no treatment. All animals were sarcificed 16 wk after termination of MNNG administration. Gastric mucosal lesions were noted in 11/16 Group A animals, 14/18 Group B animals, and 4/13 Group C animals; no tumors were noted in Groups D and E. Only two adenocarcinomas were noted: one in a Group A animal at sacrifice and one in a Group C animal that died 4 wk after termination of MNNG treatment. These findings indicate that ligation of the gastric artery potentiated the influence of MNNG. (17 refs)

78-3874 **Nitrosoguanidine Mutagenesis During the Yeast Cell Cycle.** (Eng) Carter, B. L. (Dept. Genetics, Univ. Dublin, Trinity Coll., Dublin 2, Ireland); Dawes, I. W. *Mutat Res* 51(2): 289-292; 1978.

Exponential cultures of yeast cells (*Saccharomyces cerevisiae*) were harvested by centrifugation and resuspended in 0.2 M potassium acetate buffer (pH 5.4) containing 500 μg/ml N-methyl-N′-nitro-N-nitrosoguanidine (MNNG) for 15 min at 30 C. Since all stages of the cycle are represented in an exponential culture, treating such a culture with MNNG for a fraction of the cycle is equivalent to treating cells at different stages of the cycle for a fraction of the cycle. The culture was then centrifuged, washed, separated according to size and stage of the cycle by zonal centrifugation, and plated for resistance to 0.4 mg/ml erythromycin. Mutation to nuclear erythromycin resistance was enhanced during nuclear DNA replication, and this enhancement depended on DNA replication taking place at the time of mutagenesis. If replication was inhibited 15 min prior to the application of mutagen by hydroxyurea, no peak of mutation was observed in that region of the cell cycle where nuclear DNA replication ordinarily occurs. In addition, in untreated cells actively replicating their DNA, there was no detectable enhancement of spontaneous mutation during the S phase. (15 refs)

78-3875 **Neoplastic Transformation of Canine Embryo Cells in Vitro by N-Methyl-N′-nitro-N-nitrosoguanidine.** (Eng) Rhim, J. S. (Microbiological Associates, Inc., Bethesda, MD, 20016); Park, D. K.; Arnstein, P.; Nelson-Rees, W. A. *Int J Cancer* 22(4): 441-446; 1978.

A cell line derived from a normal beagle embryo was treated in vitro with 0.01 or 0.1 μg/ml N-methyl-N′-nitro-N-nitrosoguanidine (MNNG) or dimethyl sulfoxide (DMSO, control). Cultures were treated for 7 days, washed, refed with carcinogen-free growth medium, and passaged every 7 days. Morphologic alteration and an abnormal growth pattern were observed in MNNG-treated cells in the seventh subculture (75-79 days after treatment); no such changes were observed in control cells. Saturation densities of cells transformed by 0.01 and 0.1 μg/ml MNNG were 3.9 x 10^5 and 2.1 x 10^5 cells/cm^2, respectively, two to four times higher than that of control cells. Transformed cells formed larger aggregates than DMSO-treated cells, and they grew in this aggregate form when suspended in liquid growth medium above an agar base. All nude mice inoculated sc with 5 x 10^6 cells treated with 0.01 μg/ml MNNG developed transplantable fibrosarcomas within 2 wk at the injection site. No tumors developed in mice inoculated with DMSO-treated cells or cells treated with 0.1 μg/ml MNNG. (21 refs)

78-3876 **Induction of Intestinal Metaplasia in the Stomachs of Rats by N-Methyl-N′-nitro-N-nitrosoguanidine.** (Eng) Matsukura, N. (Natl. Cancer Center Res. Inst., Tsukiji, Chuo-ku, Tokyo 104, Japan); Kawachi, T.; Sasajima, K.; Sano, T.; Sugimura, T.; Hirota, T. *J Natl Cancer Inst* 61(1): 141-144; 1978.

The induction of intestinal metaplasia was studied in the stomachs of male Wistar rats given N-methyl-N′-nitro-N-nitrosoguanidine (MNNG) (83 μg/ml in the drinking water) for 2, 4, 5, or 7 mo. MNNG intakes were estimated at 150, 300, 375, and 525 mg, respectively. Most of the rats were killed at 15 mo. Intestinal metaplasia was found in the stomachs of 80%-100% of the rats treated for ≥ 4 mo, of 37.5% treated for 2 mo, and of 10% of the controls. Metaplastic glands, composed of goblet cells and columnar cells with striated borders, were found in the pyloric region. Paneth's cells were found at the bottom of the metaplastic glands in a rat treated for 4 mo. The incidence of well-differentiated adenocarcinomas of the stomach was 63%-90% in rats treated with MNNG for ≥ 4 mo and 25% in those treated for 2 mo. This indicates that with po administration of MNNG, almost the same length of time is required to induce intestinal metaplasia and well-differentiated adenocarcinomas. (12 refs)

78-3877 **Croton Oil Enhancement of Skin Tumor Initiation by N-Methyl-N′-nitro-N-nitrosoguanidine: Possible Role of DNA Replication.** (Eng) Hennings, H. (In Vitro Pathogenesis Section, Experimental Pathology Branch, NCI, NIH, Bethesda, MD, 20014); Michael, D.; Patterson, E. *Proc Soc Exp Biol Med* 158(1): 1-4; 1978.

The effect of a single croton oil application between 6 hr before and 20 hr after skin tumor initiation by N-methyl -N′- nitro -N- nitrosoguanidine (MNNG) was studied to determine the relationship of DNA replication to the croton oil-induced enhancement of initiation. Female CD-1 mice received a single application of 0.5% croton oil 6 hr before or 1, 4, 8, or 20 hr after application of 4-micromoles of MNNG. There was a threefold increase in papilloma yield and a substantial decrease in the latent period (from 30 to 17-24 wk) when croton oil was applied at any of the times tested. Since DNA replication was not stimulated by croton oil until 2-4 days after application of MNNG, this enhancement cannot be explained by an increased uptake of the MNNG by DNA-synthesizing cells or by an increased susceptibility of these cells. If DNA replication is involved in initiation, these results suggest that the critical DNA replication occurs after the interaction of MNNG with DNA but before the initial damage can be repaired, perhaps resulting in a nonrepairable mutation. (16 refs)

78-3878 **Kinetic Studies on the Hepatic Microsomal Metabolism of Dimethylnitrosamine Diethylnitrosamine, and Methylethylnitrosamine in the Rat.** (Eng) Chau, I. Y. (Dept. Nutrition and Food Science, Massachusetts Inst. Technology, Cambridge, MA, 02139); Dagani, D.; Archer, M. C. *J Natl Cancer Inst* 61(2): 517-521; 1978.

The kinetics of the oxidative dealkylation of dimethylnitrosamine (DMN), diethylnitrosamine (DEN), and methylethylnitrosamine (MEN) by male Sprague-Dawley rat liver microsomes and the mutual interactions of these compounds were studied by a colorimetric assay that allows simultaneous measurement of formaldehyde and acetaldehyde formation. The rats were treated with 0.1% phenobarbital for 7 days before sacrifice. The substrate concentration ranges used, 38-193 mM DMN, 4-44 mM DEN, and 10-104 mM MEN, were determined primarily by the sensitivity of the aldehyde assays. For each substrate, liberation of aldehyde followed simple Michaelis-Menten kinetics. DEN had an apparent Michaelis constant (Km) value that was more than an order of magnitude smaller than that for DMN. The Km values for the demethylation and deethylation of MEN were intermediate between those for DMN and DEN. Thus, MEN was dealkylated efficiently by liver enzyme; this is consistent with the observation that, under similar conditions, DMN, DEN, and MEN are all liver carcinogens in the rat. DMN demethylase was inhibited by DEN and DEN deethylase was inhibited by DMN; in both cases, the inhibition was of a mixed type. (28 refs)

78-3879 **Selective Sex-related Modification of Diethylnitrosamine-induced Carcinogenesis in BALB/c Mice by Concomitant Administration of Butylated Hydroxytoluene.** (Eng) Clapp, N. K. (Biology Div., Oak Ridge Natl. Lab., P.O. Box Y, Oak Ridge, TN, 37830); Tyndall, R. L.; Satterfield, L. C.; Klima, W. C.; Bowles, N. D. *J Natl Cancer Inst* 61(1): 177-182; 1978.

Tumor induction by diethylnitrosamine (DENA) and its modification by butylated hydroxytoluene (BHT) were studied in BALB/c mice. BHT (0.75%) was added to the regular chow of one group of 8-wk-old mice and administered for life. A second group was given DENA in the drinking water (4 mg/100 ml) beginning at 11 wk of age for 7 wk (mean dose consumed, 330 mg/kg). Another group received BHT + DENA, and a fourth group was given untreated food and water. Female mice killed at 13.5 mo after DENA exposure had higher incidences of forestomach and lung tumors than did males, and they also had higher numbers of lung tumors per tumor-bearing mouse. Neither sex developed stomach tumors spontaneously, but males had higher incidences of spontaneous lung tumors than females (45% vs 26%). Females receiving BHT + DENA had an increased survival (68% vs 43%) and a reduced incidence of forestomach squamous cell carcinomas (77% vs 100%) compared with females There was no such protective effect on survival or on the occurrence of stomach tumors in males given BHT + DENA, and there was no such effect on lung tumorigenesis in either sex. In males, but not in females, BHT given alone increased survival time of treated mice over untreated control. The results suggest an hormonal influence and/or dependence on the protective action of BHT. (18 refs)

78-3880 **Preliminary Observations on Amines and Nitrosamines in Non-normal Human Gastric Contents.** (Eng) Lakritz, L. (U.S. Dept. Agriculture, Eastern Regional Res. Center, Philadelphia, PA); Wasserman, A. E.; Gates, R.; Spinelli, A. M. *IARC Sci Publ* (19): 425-431; 1978.

Gastric contents from 35 patients undergoing routine clinical gastric examination were assayed for amines and nitrosamines (NA's). A number of samples were tested for NA's before and/or after stimulation with histamine or pentagastrin, making a total of 57 samples analyzed. N-Nitrosodiethylamine (5-30 μg/kg) was present in four samples, N-nitrosodimethylamine (2 μg/kg) in two, and N-nitrosopyrrolidine (6 μg/kg) in one. Twenty-two of the gastric samples in which NA's were absent averaged 1.1 mg/kg nitrite and 23.7 mg/kg nitrate. Three samples in which NA's were detected were also analyzed for nitrite and nitrate, and 2/3 (from the same patient) contained about 70 mg/kg nitrite. There did not appear to be a relationship between the NA content and the pH of the gastric samples. The volatile amines found included dimethylamine, trimethylamine, and histamine. The nonvolatile amines detected were cadaverine, putrescine, ethanolamine, and tryptamine. A partial breakdown of the diagnoses for these patients includes: duodenal ulcer, 8; gastric ulcer, 1; peptic ulcer, 2; esophagitis, duodenitis, and gastritis, 4; and diabetes, cirrhosis, and anemia (numbers not given). There was no correlation between medical diagnosis and the presence of NA's in the gastric contents. (11 refs)

78-3881 **Tumor Induction by N-Nitroso Compounds in Bivalve Mollusks *Unio pictorum*.** (Eng) Khudoley, V. V. (N. N. Petrov Res. Inst. Oncology, Leningrad 188646, USSR); Syrenko, O. A. *Cancer Lett* 4(6): 349-354; 1978.

Exposure of bivalve mollusks (*Unio pictorum*) to diethylnitrosamine (DENA) and dimethylnitrosamine (DMNA) dissolved in the tank water resulted in tumor formation. DENA induced tumors in 18% of the animals exposed to 200 ppm for 64 days and 68% of those exposed to 400 ppm for 62 days; the av latent periods were 71 and 61 days, respectively. DMNA induced tumors in 8% of the animals exposed to 200 ppm for 51 days and 27% of those exposed for 152 days, and av latent periods were 85 and 81 days, respectively. Neoplasms were observed in the digestive gland (basophilic cell tumors; 38 cases), the hemopoietic system (hemocytoblastoma; 12 cases), and the kidney (poorly differentiated carcinoma; 1 case). Tumors arose from the digestive glands on a background of diffuse and focalproliferation of basophilic cells. They were invasive and characterized by extraordinary pleomorphisms and atypia. Tumor incidence was dose-dependent.It is suggested that mollusks can be used to determine the carcinogenicity of N-nitroso compounds and to indicate possible water pollutants. (9 refs)

78-3882 **Effect of Dimethylnitrosamine Concentration on Its Demethylation by Liver Microsomes from Control and 3-Methylcholanthrene Pretreated Rats, Hamsters and Guinea Pigs.** (Eng) Lotlikar, P. D. (Fels Res. Inst., Temple Univ. Medical Sch., Philadelphia, PA, 19140); Hong, Y. S.; Baldy, W. J. *Cancer Lett* 4(6): 355-361; 1978.

The effect of dimethylnitrosamine concentration on its demethylation by liver microsomes from control and 3-methylcholanthrene pretreated (100 mg/kg ip 24 hr before sacrifice) Sprague-Dawley rats, Syrian hamsters and albino guinea pigs was investigated. At a low substrate concentration (2 mM), liver microsomes from pretreated rats and hamsters showed 30%-50% lower demethylation activity than their respective controls. No such difference was found in the guinea pig. At a high substrate concentration (100 mM), all three pretreated species showed 50%-100% higher enzyme activity than their respective controls. Enzyme activities among the three species showed the following order of activity: hamster > guinea pig > rat. The DMN concentration-dependent differential DMN demethylating activities found may be due to the presence of enzymes having different affinities for DMN. (22 refs)

78-3883 **Differential Effects of β-Naphthoflavone and Pregnenolone-16α-carbonitrile on Dimethylnitrosamine-induced Hepatocarcinogenesis.** (Eng) Argus, M. F. (Seamen's Memorial Res. Lab., Biochemistry Section, U.S. Public Health Service Hosp., 210 State St., New Orleans, LA, 70118); Hoch-Ligeti, C.; Arcos, J. C.; Conney, A. H. *J Natl Cancer Inst* 61(2): 441-449; 1978.

The effect of simultaneous administration of β-naphthoflavone (NF) or pregnenolone-16α-carbonitrile (PCN) on the hepatocarcinogenicity of dimethylnitrosamine (DMN) was investigated in male SD rats. Both NF and PCN are potent inhibitors of DMN demethylase I, a low-Michaelis-constant, mixed-function oxidase believed relevant to the in vivo metabolic activation of DMN. DMN in tap water was administered via stomach tube 5x/wk for 28 wk (400 μg/rat/administration). NF or PCN (25 mg/kg) was administered in laboratory chow. Three groups of rats were treated with DMN, NF, or PCN alone. DMN-induced hepatocarcinogenesis was inhibited by PCN and enhanced by NF. Liver tumors developed in 14/43 DMN rats, 32/43 DMN + NF rats, and 7/45 DMN + PCN rats. Neither untreated controls, 32 rats receiving NF, nor 28 rats receiving PCN developed liver tumors. Although DMN + NF increased the number, invasiveness, and dissemination of tumors compared with DMN alone, the latent period was not affected. PCN decreased the absolute number of liver tumors and increased the latent period, but tumor invasiveness and dissemination were increased. Of the total 53 tumors, 28 were vascular in origin, a change in the usual morphology of DMN-induced liver tumors. Four possible explanations for the unexpected enhancement of DMN-induced hepatocarcinogenesis by NF are given. The differential effects of NF and PCN prompt a reexamination of the unique role attributed to DMN demethylase in the metabolic activation of DMN. (58 refs)

78-3884 **The Influence of DDT on Metabolism of Dimethylnitrosamine in Rats.** (Eng) Syrowatka, T. (State Inst. Hygiene, 00-791 Warsaw, Poland); Wiadrowska, B. *Toxicol Appl Pharmacol* 44(2): 219-224; 1978.

The in vitro metabolism of dimethylnitrosamine (DMNA) by liver cell preparations from untreated rats and rats given two to eight ip injections of DDT (1,1,1-trichloro-2,2-bis(p-chlorophenyl)ethane: 50 mg/kg, every second day) or a single ip injection of 3-methylcholanthrene (MC: 100 mg/kg) was studied. The activity of O-demethylase in the liver postmitochondrial supernatant was measured as an overall indicator of microsomal enzyme induction. Compared with controls, only the preparations from rats given eight injections of DDT showed significant differences in the rate of DMNA metabolism. O-Demethylase activity was significantly different among preparations from all treated groups, and the activity in these preparations differed significantly from that of controls. The greatest increases in activity were in the preparations from rats treated with MC or two doses of DDT. However, there was no correlation between the rate of DMNA metabolism and O-demethylase activity with the preparations. When DMNA (40 mg/kg) was administered ip to the DDD-treated rats 24 hr after the last injection, no DMNA was detected in the blood 8 hr later. The data suggest that the induction of liver microsomal enzymes by DDT exerts only a slight effect on the rate of DMNA metabolism in vitro and in vivo. (13 refs)

78-3885 **A Sensitive Method for the Colorimetric Determination of Volatile Nitrosamines in Food Products and Air.** (Eng) Ceh, L. (Dept. Biochemistry, Veterinary Coll. Norway, P.O. Box 8146, Dep. Oslo 1, Norway); Ender, F. *Food Cosmet Toxicol* 16(2): 117-121; 1978.

Volatile nitrosodialkylamines (NDA's) were extracted from foods containing at least 0.1 μg NDA (preferably 1-10 μg) with freshly distilled water and purified and concentrated by distillations from alkaline and acid soln. The nitrosamines were then reduced with granulated Zn and HCl and oxidized to monoalkylhydrazines by heating and evaporating the soln to a volume of 3-5 ml. Following this, the oxidized compounds were coupled with p-dimethylaminobenzaldehyde. The absorbance of the resulting alkylaldazine complex was measured at 458 nanometers (nm). A calibration curve was obtained by carrying out this procedure with N-nitrosodimethylamine (NDMA), the most common NDA found in food and feed materials. Photometry at 458 nm allowed the determination of as little as 0.1 μg NDMA. Higher nitrosoalkylamines were as efficiently reduced by Zn and HCl as was NDMA. The method was equally sensitive when it was used to determine nitrosamines in laboratory and storeroom air. (16 refs)

78-3886 **Dimethylnitrosamine Inhibits Enzymatic Removal of O^6-Methylguanine from DNA.** (Eng) Pegg, A. E. (Dept. Physiology, Milton S. Hershey Medical Center, Pennsylvania State Univ., 500 University Drive, Hershey, PA, 17033). *Nature* 274(5667): 183-184; 1978.

Liver and kidney extracts from control rats and rats treated with dimethylnitrosamine (DMN: 20 mg/kg) were tested for their ability to catalyze the loss of 0^6-methylguanine (O-MG) from acid-precipitable DNA in vitro. The extracts were incubated with calf thymus DNA that had been alkylated by reaction with ^{3}H-N-methyl-N-nitrosourea or with rat liver

DNA that had been alkylated in vivo by an injection of H-DMN (50 μg/g) shortly before death. None of the exracts resulted in the loss of 7-methylguanine or guanine from he acid-precipitable DNA. Liver extracts were more active han kidney extracts in catalyzing the removal of O-MG, but with both tissues the activity was lost if the rats had been pretreated with 20 mg/kg DMN. Extracts from the nitrosamine-treated rats were still inactive after a purification step nvolving chromatography on 2-(diethylamino)ethanol celulose. The findings suggest that high doses of alkylating carcinogens inhibit the hepatic and renal enzyme systems that are involved in the removal of O-MG from DNA. This inhibitory action may be important in the induction of tumors by nitroso compounds. (13 refs)

78-3887 **Formation of Nitrosodimethylamine by Microorganisms Used in the Baking Industry or Isolated from the Raw Materials of Bakery Products.** (Eng) Uibu, J. (Inst. Experimental and Clinical Medicine, Tallinn, Estonia); Bogovski, P.; Tauts, O. *IARC Sci Publ* (19): 247-256; 1978.

The production of N-nitrosodimethylamine (NDMA) by microorganisms used in the baking industry and the presence of NDMA in the raw materials of bakery products were investigated. Among the 22 strains of bacteria and fungi studied, 7 produced NDMA: 2 of *Saccharomyces cerevisiae* used in the baking industry; 2 of *Pseudomonas*, one from rye flour and one from compressed baker's yeast; and a strain of *Bacillus subtilis* isolated from leaven. NDMA production was not a property of a particular species but rather of various biotypes. All bacterial NDMA producers showed nitrate reductase activity, but not all nitrate-reducing microorganisms produced NDMA. Two strains of *S. cerevisiae* produced NDMA without any of this enzyme activity. Prolonged incubation time was desirable for detecting microbial producers of nitrosamines. The yield of NDMA produced by a *Pseudomonas* strain was reduced in the presence of 0.1% and 1% flour; however, at higher percentages, the yield increased and remained constant to 10%. In contrast, NDMA production by *P. herbicola* decreased as the amount of crushed wheat was increased, a result that may be related to the tendency of the pH to increase when more wheat was added. Although the cultivation conditions used were far from those occurring in a bakery plant, the data strongly indicate the need for more research concerning nitrosamine formation in bakery products. (17 refs)

78-3888 **Interactions of 4-Nitroquinoline 1-Oxide with Four Deoxyribonucleotides.** (Eng) Winkle, S. A. (Dept. Chemistry, Univ. California, Berkeley, CA, 94720); Tinoco, I. *Biochemistry (Washington)* 17(7): 1352-1356; 1978.

The interactions of 4-nitroquinoline l-oxide (NQO) with the four 5′-deoxyribonucleotides were probed using absorption spectra of the charge transfer bands and ^{1}-H and ^{13}C nuclear magnetic resonance spectra of nucleotide-NQO mixtures. Using Benesi-Hildebrand-type plots, the equilibrium constants for the formation of 1:1 complexes of deoxyguanosine 5′-monophosphate, deoxyAMP, deoxythymidine ′-monophosphate, and deoxycytidine 5′-monophosphate and NQO were obtained. These equilibrium constants, which are similar in value to those obtained for the deoxynucleosides, indicate the preference of NQO for the guanine residues of DNA. NQO, rather than a possible metabolite such as 4-hydroxyaminoquinoline 1-oxide, could possibly be the species that interacts with the bases of DNA. A previous electron spin resonance study on NQO free radicals showed that DNA enhanced the formation of NQO free radicals, which might suggest that DNA helps metabolize the NQO to an adduct-forming species. These studies indicate the feasibility of using NMR and optical methods for studying complexing of NQO with dinucleotides. (17 refs)

78-3889 **Lethal and Mutagenic Action of a Carcinogen 4-Nitroquinoline 1-Oxide on *Chaetomium aureum* Chivers.** (Eng) Ghora, B. K. (Washington Univ., Sch. Medicine, Dept. Microbiology, Box 8093, St. Louis, MO, 63110); Chaudhuri, K. L. *Science Culture* 43(8): 357-359; 1977.

The effects of 4-nitroquinoline 1-oxide (4NQO) on *Chaetomium aureum* fungi were investigated. Doses of 16.0 x 10^{-6} M 4NQO drastically reduced the survival rate of *C. aureum*, but a much smaller reduction was noted with 16.0 x 10^{-7} M. The mutagenic action of the compound also increased with increasing dose; max mutagenicity was noted at 16.0 x 10^{-6} M. All mutants lost their cellulase producing ability. (12 refs)

78-3890 **N-Nitroso-3-hydroxypyrrolidine in Fried Bacon and Fried Out Fat.** (Eng) Lee, J. S. (Dept. Food Science and Technology, Oregon State Univ., Corvallis, OR); Libbey, L. M.; Scanlan, R. A.; Barbour, J. *IARC Sci Publ* (19): 325-332; 1978.

A new method for the trace analysis of N-nitroso-3-hydroxypyrrolidine (NHPYR) in fried bacon and fried-out fat is described. For the identification study, five commercial brands of raw bacon were obtained. For recovery studies, six replicate analyses were performed on fried nitrite-free bacon and fried-out fat that had been spiked with 10 ppb NHPYR. NHPYR was extracted from the sample with water:methanol (3:2). After elimination of residual nitrite with ammonium sulfamate, NHPYR was removed from the water:methanol by continuous extraction with dichloromethane. Identification was accomplished by conversion of NHPYR to the trimethylsilyl derivative, followed by separation on a capillary column and characterization by gas chromatography-mass spectrometry. Concentration and recovery studies were conducted without derivatization. Concentrated dichloromethane extracts were analyzed by a gas chromatograph-thermal energy analyzer system. Recovery of NHPYR from fried bacon and fried-out fat was 62% and 63%, respectively. NHPYR levels in five samples of commercial bacon were 0.4-3.0 ppb in fried bacon and 0.3-2.3 ppb in fried-out fat. Although N-nitrosopyrrolidine is a well-known carcinogen, it is not known whether NHPYR is also carcinogenic. (12 refs)

78-3891 **Trends in Levels of N-Nitrosopyrrolidine in Fried Bacon.** (Eng) Havery, D. C. (Dept. Health, Education and Welfare, Washington, DC); Fazio, T.; Howard, J. W. *IARC Sci Publ* (19): 305-310; 1978.

Nine popular brands of bacon on the Washington, DC, retail marked were analyzed for N-nitrosopyrrolidine (NNP) content from 1971 to 1977. The results show that there was a significant decline in NNP content in six brands during 1971-1974. Since 1974, there has been little change in NNP levels. Additional progress in eliminating NNP may be difficult if botulinum control is to be maintained. Substitutions for nitrite are currently under investigation. (5 refs)

78-3892 **Comparative Mutagenesis of Nitrosopiperidines (Meeting Abstract).** (Eng) Nix, C. E. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37820); Rao, T. K.; Larimer, F. W.; Epler, J. L. *Mutat Res* 53(2): 243; 1978. (no refs)

78-3893 **Determination of N-Nitrosoproline in Meat Samples.** (Eng) Baker, J. K. (Dept. Medicinal Chemistry, Sch. Pharmacy, Univ. Mississippi, University, MS, 38677); Ma, C. Y. *J Agric Food Chem* 26(5): 1253-1255; 1978.

A combination of high-pressure liquid chromatography and thermal energy analysis for the determination of N-nitrosoproline (NPRO) in meat was shown to have sufficient accuracy and moderate precision in spiked samples containing 100 ppb NPRO. Application of the method to commercial meat samples revealed that some contained very low levels of NPRO. (12 refs)

78-3894 **The Results of Pancreatography During Pancreatic Carcinogenesis.** (Eng) Takahashi, M. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, 42nd and Dewey Ave., Omaha, NB, 68105); Pour, P. *Am J Pathol* 91(1): 57-70; 1978.

Systematic histologic-pancreatographic examinations were performed during induced pancreatic carcinogenesis in Syrian golden hamsters to define relevant criteria for tumor detection at early stages. The hamsters were given weekly s injections of N-nitrosobis(2-oxopropyl)amine (10 mg/kg) fo up to 9 wk. Animals were killed beginning 2 wk after the fift injection and at 2-wk intervals thereafter. Immediately afte death, India ink was injected into the pancreatic duct, an the specimen was processed for photography and histologi evaluation. Ductal changes due to hyperplasia of ductal epithelium were recognized as distention rather than narrowing but this condition occurred in limited numbers during advanced ductal alteration and was an insignificant criterion The most reliable tumor marker was complete ductal obstruction: ductal deterioration (displacement, deformity) occurred in 63% of the tumor cases, a pooling effect in 44% and a filling defect in 42%. The "chain of lakes" caused b ductular proliferation or adenomas, both of which seem t represent precursor stages of adenocarcinomas, was seen i both histologic and pancreatographic studies. Some neoplasms escaped diagnosis because of their small size, anatomic location, or specific histologic patterns. It is concluded tha pancreatography is unreliable as an early detection techniqu for induced pancreatic cancer and that additional clinica parameters are required. (19 refs)

78-3895 **Zinc Deficiency and Methylbenzylnitrosamine-induced Esophageal Cancer in Rats.** (Eng Fong, L. Y. (Dept. Biochemistry, Univ. Hong Kong, Hon Kong); Sivak, A.; Newberne, P. M. *J Natl Cancer Inst* 61(1) 145-150; 1978.

The role of zinc deficiency in esophageal cancer induced b methylbenzylnitrosamine (MBN) was studied in male outbred Charles River CD rats fed a control (containing 60 pp Zn) or a Zn-deficient (7 ppm Zn) diet. Groups of control an Zn-deficient rats were given 24, 17, 8, or 4 doses of MBN b intragastric intubation (2 mg/kg 2x/wk). All rats were kille and examined at 58-93 days after the beginning of treatment All rats receiving 24 doses of MBN beginning at 15 wk developed tumors; however, 43% of the tumor in Zn-deficien group were invasive carcinomas compared with 15% in th controls. After 17 doses beginning at 7 wk of age, all of th Zn-deficient rats at both 58 and 93 days and 33% and 66% of the control rats developed tumors. However, none of th controls developed invasive carcinoma, compared with 83% of the Zn-deficient rats sampled at 58 days and 33% sample at 93 days. Following ip injection of methyl-^{14}C-MBN, th DNA and RNA of esophagus and liver were more noticeabl labeled than the DNA and RNA of kidney, lung, and smal intestine. In vitro incubation of tissue slices from esophagus liver, kidney, and small intestine with ^{14}C produced simila results. These results indicate that Zn deficiency increases th incidence of and shortens the lag time for induction of esophageal tumors by MBN. Since Zn usually interacts wit other trace elements, these findings imply that the observe effects involve a trace element imbalance on a broader scale (20 refs)

78-3896 **Effect of Phenacetin and Caffeine on the Urinary Bladder of Rats Treated with N-Butyl-N-(4-hydroxybutyl)nitrosamine.** (Eng) Nakanishi, K. (First Dept. Pathology, Nagoya City Univ. Medical Sch., 1 Kawasumi, Mizuho-cho, Mizuho-ku, Nagoya 467, Japan); Fukushima, S.; Shibata, M.; Shirai, T.; Ogiso, T.; Ito, N. *Gann* 69(3): 395-400; 1978.

The effect of phenacetin and caffeine on urinary bladder carcinogenesis was evaluated in male Wistar rats treated with N-butyl-N-(4-hydroxybutyl)nitrosamine (BBN). Animals were given a high (0.05%) or (0.01%) low dose of BBN for 4 wk and then phenacetin (2.5% in diet) or caffeine (0.1% in drinking water) was administered for 30 and 32 wk, respectively. All the animals were examined histologically after 36 wk. The incidence of papillary or nodular hyperplasia, papilloma, and cancer of the urinary bladder was significantly higher in the groups treated with BBN + phenacetin, especially in the group treated with 0.05% BBN + phenacetin, than in those treated with BBN alone. Simple hyperplasia and papillary or nodular hyperplasia developed in the urinary bladder of rats treated with phenacetin alone. Papillary proliferative growth of the renal pelvis was seen in one rat treated with a 0.01% BBN + phenacetin. Treatment with BBN + caffeine had no enhancing effect, and caffeine alone caused no remarkable changes. The results show that phenacetin enhanced BBN carcinogenesis and that this effect was additive. (18 refs)

78-3897 **Chemical Studies on Tobacco Smoke. LVI. Tobacco Specific Nitrosamines: Origins, Carcinogenicity and Metabolism.** (Eng) Hecht, S. S. (Naylor Dana Inst. Disease Prevention, American Health Foundation, Valhalla, NY); Chen, C. B.; Ornaf, R. M.; Hoffmann, D.; Tso, T. C. *IARC Sci Publ* (19): 395-413; 1978.

The formation, occurrence, and carcinogenicity of tobacco-specific nitrosamines are reviewed. The major tobacco-specific nitrosamine is N′-nitrosonornicotine (NNN), which is present in both unburned tobacco (0.3-90.6 ppm) and cigarette mainstream smoke (127-238 nanograms/cigarette). Model studies of the reaction of nicotine and nitrite showed that two other nitrosamines could be formed under mild conditions: 4-(N-methyl-N-nitrosamino) -4- (3-pyridyl) -1- butanal (NAA) and 4-(N-methyl -N-nitrosamino) -1- (3-pyridyl) -1- butanone (NNK). NNK was detected in both chewing tobacco and snuff. A comparative bioassay of NNN, NNK, and NNA in strain A mice indicated that NNK was more tumorigenic than NNN and that NNA was inactive. Sc injections of NNN into male and female Syrian golden hamsters (3x/wk for 25 wk; total dose, 375 mg) induced tracheal tumors in 12/19 hamsters within 83 wk. In a study of the metabolism of cyclic nitrosamines, metabolic α-hydroxylation of nitrosopyrrolidine, which is thought to be the critical step in activation of this compound, was demonstrated by detection in vitro and in vivo of 2-hydroxytetrahydrofuran, the decomposition product of α-hydroxynitrosopyrrolidine. (38 refs)

78-3898 **The Mutagenicity of Heterocyclic N-Nitrosamines for *Salmonella typhimurium*.** (Eng) Zeiger, E. (Environmental Mutagenesis Branch, Natl. Inst. Environmental Health Sciences, P.O. Box 12233, Research Triangle Park, NC, 27709); Sheldon, A. T. *Mutat Res* 57(1): 1-10; 1978.

Fourteen carcinogenic and noncarcinogenic heterocyclic N-nitrosamines were evaluated for mutagenicity to *Salmonella typhimurium* TA1535, which responds to mutagens inducing base-pair substitutions. The nitrosamines tested were N-nitrosomorpholine (NM), 2,6-dimethyl-N-nitrosomorpholine (DMNM), N-nitrosothiomorpholine (NTM), 1-nitrosopiperazine (NPIPZ), 1,4-dinitrosopiperazine (DNPIPZ), 1-methyl-4-nitrosopiperazine (NMPIPZ), 2,6-dimethyl-1,4-dinitrosopiperazine (DMDNPZ), N-nitrosoazetidine (NAZ), N-nitrosopyrrolidine (NPYRR), N-nitrosopiperidine (NPIPD), N-nitrosohexamethyleneimine (NHMI), N-nitrosoheptamethyleneimine (NHPMI), N-nitrosooctamethyleneimine (NOMI), and N-nitrosododecamethyleneimine (NDMI). Both suspension and plate tests were used with mouse and rat liver metabolic activation systems. All nitrosamines tested, both carcinogenic and noncarcinogenic, showed a positive response in at least one test system. Among the nitrosomorpholine derivatives, NM was the most active mutagen in all systems, followed by DMNM and NTM. NPIPZ was the least mutagenic nitrosopiperazine tested. The series of compounds between NAZ through NOMI had a high level of mutagenic activity, but NDMI did not. The mutagenic responses obtained with mouse liver were generally equal to, or greater than, the responses obtained with rat liver in both the suspension and plate tests. Although it is difficult to make quantitative comparisons between plate and suspension tests, both systems appeared to be responsive to the same dose ranges for the individual nitrosamines. (29 refs)

78-3899 **N-Nitroso-5-methyl-1,3-oxazolidine Identified as an Impurity in a Commercial Cutting Fluid.** (Eng) Stephany, R. W. (Natl. Inst. Public Health, Bilthoven, Netherlands); Freudenthal, J.; Schuller, P. L. *Rec Trav Chim Pays Bas* 97(6): 177-178; 1978.

A commerical mineral oil cutting fluid concentrate was found, by various chromatographic analyses, to contain 30 mg/kg N-nitroso-5-methyl-1,3-oxazolidine. Identification was by gas chromatography-mass spectrometry using reference compounds. The N-nitrosamine, whose parent compound is a strong liver carcinogen, may have been formed from 1-amino-2-propanol. (6 refs)

78-3900 **The Effect of Carcinogens on the Nuclear Size of HeLa Cells.** (Eng) Agrelo, C. E. (British Industrial Biological Res. Assoc., Carshalton, Surrey, England). *Toxicology* 9(1/2): 21-27; 1978.

The possibility that changes in nuclear size might be used as an index of the carcinogenicity of compounds to which cells have been exposed was examined using HeLa S-3 cells. Optimal reaction conditions were the use of concentrations of chemicals that had a low order of cytotoxicity and the measurement of nuclear size 48 hr after pulse treatment of the cells for 30-60 min. When necessary for activation, rat liver microsome preparations were added. After exposure of HeLa S-3 cells to N-methyl-N-nitrosourea, N-dimethylnitrosamine, vinyl chloride, aflatoxin B$_1$, mitomycin C, or acetoxydimethylnitrosamine, nuclear size increased and the frequency distribution pattern of nuclear size changed. The increase in nuclear size was usually dose-related. These effects were not seen with noncarcinogens. The results suggest that changes in nuclear size may be an index of chemical carcinogenicity. (18 refs)

78-3901 **Induction of Tumors in Heterotopic Bladder by Topical Application of N-Methyl-N-nitrosourea and N-Butyl-N-(3-carboxypropyl)nitrosamine.** (Eng) Oyasu, R. (Dept. Pathology, Northwestern Univ. Medical Sch., Chicago, IL, 60611); Iwasaki, T.; Matsumoto, M.; Hirao, Y.; Tabuchi, Y. *Cancer Res* 38(9): 3019-3025; 1978.

Bladders from CD Fischer rats were transplanted into the gluteal muscle of rats of the same strain and connected to a reservoir implanted into the sc tissue at the back. This system is a potentially useful model for bladder carcinogenesis studies. Two carcinogens, N-methyl-N-nitrosourea (MNU) and N-butyl-N-(3-carboxypropyl)nitrosamine (BCPN), were instilled repeatedly into the reservoir connected with the heterotopic bladder. Transitional cell carcinomas developed in 25/33 heterotopic bladders exposed to cumulative doses of 1.5, 3.0 or 6.0 mg MNU for 20-30 wk, but heterotopic bladders exposed to cumulative doses of 150 or 300 mg BCPN failed to develop tumors. However, 11/27 rats with heterotopic bladders that were exposed to BCPN for $>$ 20 wk developed tumors in their homotopic or natural bladders. MNU probably acted directly on the bladder epithelial cells to induce neoplastic change. The reason(s) for the development of tumors in the homotopic but not heterotopic bladders when BCPN was administered directly into the heterotopic bladders could not be ascertained. (18 refs)

78-3902 **Pathogenesis of Rat Colon Carcinomas Induced by N-Methyl-N-nitrosourea.** (Eng) Lev, R. (Dept. Pathology, Roger Williams General Hosp., 825 Chalkstone Ave., Providence, RI, 02908); Herp, A. *J Natl Cancer Inst* 61(3): 779-786; 1978.

Colon specimens were obtained from 45 young male and female inbred CDF rats between 11 and 42 wk after they began to receive intrarectal injections of the carcinogen N-methyl-N-nitrosourea (MNU: 43-108 mg, total dose). Groups of animals were given 2 mg/wk for 1 mo, then 2.5 mg 1x or 2 x/wk for 20 wk. Specimens were also obtained from 26 control rats. Well-developed tumors from rats receiving MNU generally presented grossly as polyps and histologically as invasive adenocarcinomas that had not metastasized. These tumors resembled their human counterparts. Focal epithelial atypias were found in grossly normal mucosa both from rats that had not yet developed tumors and from tumor-bearing rats. These foci typically consisted of low columnar cells with enlarged nuclei, increased number of mitoses, cytoplasmic basophilia, and reduced cytoplasmic mucus. Serial section studies of minute foci of atypia indicated that some of them arose from normal deep crypt cells. Transitions were frequently found between atypical foci and in situ or invasive carcinomas. Less commonly, adenomatous epithelium was identified in the early lesions or within the frank adenocarcinomas. It was concluded that most invasive carcinomas in this rat model originate in foci of epithelial atypia, which are found with increasing frequency in the flat mucosa during treatment with MNU, but that some carcinomas also arise from adenomatous epithelium. (25 refs)

78-3903 **In Vivo DNA Repair after N-Methyl-N-nitrosourea Administration to Rats of Different Ages.** (Eng) Arfellini, G. (Istituto di Cancerologia, Universita di Bologna, via S. Giacomo 14, 40126 Bologna, Italy); Grilli, S.; Prodi, G. *Z Krebsforsch* 91(2): 157-164; 1978.

In vivo DNA repair was studied in female Wistar rats inoculated ip with N-methyl-N-nitrosourea (MNU: 0.1 mg/g) at age 10 days, age 2 mo, or on the 18th day of pregnancy. The rats received 12 im injections of ^{3}H-thymidine (0.75 μCi/g) before being killed 8, 15, or 22 hr after MNU treatment. Hydroxyurea (0.5 mg/g) was also administered prior to sacrifice (3 ip injections) to inhibit scheduled DNA synthesis. In young adult liver, DNA repair was complete by 22 hr, the time at which repair began in newborn rat liver. Liver DNA repair was max at 15 hr in the pregnant rats, but it was undetectable in their fetuses. There was no evidence of DNA repair in the kidney and brain (MNU target organs) of rats from the different age groups. The higher sensitivity of the fetus and the neonate to the oncogenicity of MNU may be partly due to an impairment in DNA repair. (22 refs)

78-3904 **Histochemistry of Acid Mucopolysaccharides During the Genesis of Brain Tumors Induced in Rats by Methylnitrosourea.** (Ger) Engelhardt, A. (Abteilung fur Cytopathologie, Institut fur Experimentelle Pathologie am Deutschen Krebsforschungszentru, Postfach, D-6900 eidelberg, W. Germany); Bannasch, P. *Acta Neuropathol* *Berl)* 42(3): 197-204; 1978.

arly histologic and histochemical changes that occurred uring the genesis of brain tumors induced in 66 Wistar rats y chronic iv administration of methylnitrosourea (5 ng/kg/wk) were studied. After a lag period of 225-300 days, 0 CNS tumors developed: 8 gliomas, 33 gliomatous microtunors, 8 sarcomas, 5 sarcomatous microtumors, and 6 eurinomas. In addition, 15 areas with characteristic histohemical changes, but without cell proliferation, were found. cid mucopolysaccharides could be demonstrated in these reas by the iron binding reaction or by Alcian Blue staining eaction (Alcian-positive areas without cell proliferation). he same histochemical changes were seen in all gliomatous nicrotumors (Alcian-positive areas with cell proliferation) nd in fully developed gliomas. The positive staining reaction or acid mucopolysaccharides was diffuse or weblike. In the enter of the larger gliomas, Alcian positivity tended to disapear. Alcian-positive areas with and without cell proliferation nd fully developed gliomas showed a similar localization: hey involved preferentially the white matter and regions near he lateral ventricles. These observations show that gliomas riginate from Alcian-positive areas rich in acid mucopolyaccharides. The histochemical findings point to an early disegulation of carbohydrate metabolism during the neoplastic ransformation of glial cells. In contrast to gliomas, sarcomas ever accumulate acid mucopolysaccharides. This histohemical difference may help to distinguish between gliomas nd sarcomas. (36 refs)

8-3905 **Nitrosourea-induced Brain Tumors: An In Vivo and In Vitro Tumor Model System.** (Eng) Yohida, J. (Dept. Neurosurgery, Sch. Medicine, New York Jniv. Medical Center, 550 First Ave., New York, NY, 0016). *J Natl Cancer Inst* 61(2): 365-374; 1978.

he tumorigenicity of methylnitrosourea-induced glioma nd an ethylnitrosourea-induced neurinoma was subtantially increased when the tumors were serially subultured in vitro or serially transplanted sc in 30-day-old DF rats. In early passages, the two tumor types were readily listinguishable, but after 10 in vivo passages and 20 in vitro assages, the cells became indistinguishable. However, basic lifferences could be demonstrated electron microscopically fter as many as 87 in vitro passages. The tumorigenicity (in ransplantation experiments) of these tumors was classified nto four grades: (I) negative tumorigenicity; (II) positive but ot consistent tumorigenicity; (III) consistent 100% umorigenicity but erratic tumor latency period; (IV) consistnt 100% tumorigenicity with consistent tumor latency perid. The neurinoma required a lower number of in vivo and n vitro passages to obtain Grade IV tumorigenicity than did he glioma. In transplantation experiments, immunosuppresion (nonlethal whole-body x-radiation or neonatal thymectomy) of the mice hastened tumor appearance significantly compared with that in untreated controls. (24 refs)

78-3906 **Analysis of N-Ethyl-nitrosourea-induced Brain Carcinogenesis by Sequential Culturing During the Latent Period. I. Morphology and Tumorigenicity of the Cultured Cells and Their Growth in Agar.** (Eng) Roscoe, J. P. (Sch. Pathology, Middlesex Hosp. Medical Sch., Riding House St., London W1P 7LD, England); Claisse, P. J. *J Natl Cancer Inst* 61(2): 381-390; 1978.

Pregnant BD IX rats were given ip injections of 40-50 mg/kg N-ethyl -N- nitrosourea on gestation day 15 or 16, and brain cultures were prepared from fetuses and offspring at 2, 3, 5, 34-35, 57-60, 90-91, 111-112, and 138-145 days postinjection (PI). The cultures were examined for morphology, growth in soft agar, and tumorigenicity upon sc injection into syngeneic rats. From 90 days PI onward, cells resembling glioma cells were observed. These cells, termed basal layer cells (BLC), were not observed in control cultures. The BLC in cultures prepared 90-91 days PI did not persist and they did not grow in soft agar or produce tumors. From 111 days PI onward, however, the BLC predominated and they behaved like malignant cells. In general, the longer the time lapse before removal of the cells for culture, the more closely the cells resembled tumor cultures. Three main morphologic types of BLC that occurred in different proportions in the cultures were observed: fried eggs, crescents, and pyramids. The pyramidal type was associated with a shorter tumor latency; the fried egg type was predominant in cultures prepared 90-91 days PI, in which BLC disappeared upon passaging. The apparent progression with increasing malignancy is suggested to be (fried egg, crescent) -> pyramid -> less obviously pyramidal with further reduction in size. Cultures prepared < 90 days PI did not contain BLC and did not grow in agar or in animals at early passages. However, cultures derived 2 days PI became tumorigenic after prolonged culturing (>44 passages), which indicated that they had already acquired malignant potential. (18 refs)

78-3907 **Analysis of N-Ethyl-N-nitrosourea-induced Brain Carcinogenesis by Sequential Culturing During the Latent period. II. Morphology of the Tumors Induced by Cell Cultures.** (Eng) Claisse, P. J. (Sch. Pathology, Middlesex Hosp. Medical Sch., Riding House St., London W1P 7LD, England); Lantos, P. L.; Roscoe, J. P. *J Natl Cancer Inst* 61(2): 391-397; 1978.

Pregnant BD IX rats were inoculated ip with 40-50 mg/kg N-ethyl-N-nitrosourea (ENU) on gestation day 15 or 16. Cultured cells derived from brains of fetuses and offspring 2, 111-112, and 138-145 days postinjection (PI) were injected sc into syngeneic rats, and the histology of the induced tumors was compared. Some of the cultures taken at each of the PI times formed malignant growths that invaded and destroyed surrounding tissues. The tumors exhibited different structural patterns in various areas. A central area of loosely distributed, large, polygonal cells contrasted with bundles of smaller fusiform cells at the periphery. These patterns might reflect two processes occurring within the tumors: tissue organization and cellular differentiation. Three morphologic groups of cells could be distinguished: bipolar-fusiform (B-F), polygonal-stellate (P-S), and binucleate-multinucleate (B-M). Phosphotungstic acid/hematoxylin (PTAH) stains allowed separation of the B-F cells into glioblasts with weakly positive glial fibers and collagen-producing cells. P-S and B-M cells were of astrocytic derivation with evidence of glial fiber production. Varying degrees of pleomorphism were observed in all tumors; however, decreasing pleomorphism correlated well with increasing time between ENU treatment and culture initiation. Tumors from cultures derived at 2 days were the most pleomorphic although they were unmistakably glial, as demonstrated by the presence of many PTAH-staining fibrils. Cellular pleomorphism decreased with increasing number of transfers in tumors from some cultures prepared 111-112 days and 138-145 days PI, but not in those derived 2 days PI. (17 refs)

78-3908 **Chromosome Aberrations and Unscheduled DNA Synthesis in X- and UV-irradiated Lymphocytes from a Boy with Bloom's Syndrome and a Man with Xeroderma Pigmentosum.** (Eng) Evans, H. J. (MRC Clinic and Population Cytogenetics Unit, Western General Hosp., Crewe Road, Edinburgh, EH4 2XU, Scotland); Adams, A. C.; Clarkson, J. M.; German, J. *Cytogenet Cell Genet* 20(1-6): 124-140; 1978.

Blood lymphocytes from a 6.5-yr-old boy with Bloom's syndrome (BS) and a 51-yr-old man with a mild form of xeroderma pigmentosum (XP) were examined for their response to UV radiation, as measured by unscheduled DNA synthesis levels, and to x radiation, as measured by chromosome aberrations. Although the child with BS showed facial skin sensitivity to sunlight, his lymphocytes had a normal unscheduled DNA synthesis response. In contrast, cells from the XP patient showed a 50% reduction in unscheduled DNA synthesis following UV exposure. Cytogenetic studies of phytohemagglutinin-stimulated BS lymphocytes revealed a typical increase in the incidence of aberrations. Many of the cells showed breakages located at the centromere and equal, symmetrical chromatid interchanges involving homologous chromosomes. The aberrations were not produced in control cells cultured in serum from the BS patient. In contrast, the frequency aberration spontaneous in XP lymphocytes was similar to that in controls. When G_1 cells from both patients were exposed to a range of x-ray doses, they did not differ from controls in the incidence of induced chromosome-type aberrations. The significance of this finding is discussed in relation to the response of BS cells to chemical mutagens. (39 refs)

78-3909 **Repair Replication in Replicating and Non-replicating DNA after Irradiation with UV Light.** (Eng) Slor, H. (Dept. Human Genetics, Sackler Sch. Medicine, Tel-Aviv Univ., Tel-Aviv, Israel); Cleaver, J. E. *Nucleic Acids Res* 5(6): 2095-2098; 1978.

The ability of replicating and nonreplicating Hela cell DNA damaged by UV light to undergo repair replication was studied. The percentage of dimers in parental DNA strands from replicated DNA (0.147) was higher than that from the unreplicated DNA (0.032). The results suggest that more dimers are formed in replicons that are about to replicate their DNA than in the bulk DNA. About seven times more repair replication occurred on the parental strands of replicating DNA than in the bulk DNA, and it appeared that not all the parental strands were repaired to the same extent. The data indicate that replicons that replicate their DNA during the first 2-3 hr after UV irradiation contain more dimers and undergo more repair replication, involving larger patches, than do replicons that do not replicate at that time. It is possible that special conformations that may be associated with DNA replication cause a greater efficiency in dimer formation and a concomitant increase in repair replication. (11 refs)

78-3910 **Effect of Caffeine on DNA Polymerase I from *Escherichia coli*. Studies In Vitro and In Vivo.** (Eng) Solberg, K. A. (Dept. Biochemistry, Univ. Bergen, Bergen, Norway); Ovrebo, S.; Kleppe, R. K.; Kleppe, K. *Mutat Res* 51(1): 1-10; 1978.

The effect of caffeine on the activity of DNA polymerase I from *Escherichia coli* was studied. Caffeine had no effect on polymerizing activity, but it did inhibit both 5' --> 3' and 3' --> 5' nuclease activities of DNA polymerase I. The inhibition was most marked with d(A-T)n as substrate and less marked with T_7 DNA. At 10mM caffeine, inhibition was 50%. Caffeine had little effect on the ratio between mono- and dinucleotides. Sensitivity to UV irradiation and the effect of caffeine on dark repair was studied in vivo in three isogenic strains of *E. coli* carrying different mutations in the DNA polymerase I gene. The effect of caffeine on survival after UV irradiation was most marked for the wild-type, *pol+*, and less marked for the mutants defective in 3' --> 5' (*polA1*) and 5' --> 3' (*polA107*) nuclease activities. Caffeine had little effect on the survival of the *resA1* mutant, which lacks both 5' --> 3' and 3' --> 5' nuclease activities. The data support the concept that the influence of caffeine on dark repair may be explained in part by its effect on the nuclease activities of DNA polymerase I. (38 refs)

78-3911 **Postreplication Repair of DNA in Ultraviolet Light-irradiated Normal and Malignantly Transformed Mouse Epidermal Cell Cultures.** (Eng) Bowden, G. T. (NCI, NIH, Building 37, Room 3A19, Bethesda, MD, 20014); Giesselbach, B.; Fusenig, N. E. *Cancer Res* 38(9): 2709-2718; 1978.

Alkaline sucrose gradient analysis of pulse-labeled single-stranded DNA was used to study the effect of UV irradiation (wavelength, 254 nanometers; rate, 1 joule/m^2/sec) on the size of newly synthesized DNA in primary cultures of newborn C3H mouse epidermal cells and in an in vitro malignantly transformed epidermal cell line. The latter was derived by treatment of a primary culture of B10Lp mouse epidermal cells with 10^{-6} M dimethylbenz(a)anthracene. In both cell types, the DNA that was synthesized after UV irradiation was smaller. This smaller size may have been due to gaps in the newly synthesized DNA or to a slower rate of DNA polymerization. Therefore, the pulse time for the treated cells was increased so that equal amounts of DNA synthesis occurred in control and treated cells. Under these conditions, the pulse-labeled DNA's were very similar in size, which suggested that the rate of polymerization had been slowed by UV and that no gaps were present. However, it was possible that gaps were present but were being closed rapidly. Caffeine was therefore used to inhibit gap filling under conditions of equalized DNA synthesis in control and treated cells. When caffeine was present during the extended pulse, the newly synthesized DNA was again smaller in the UV-treated cells than in the control cells. According to these results, gaps do occur in newly synthesized DNA of UV-irradiated epidermal cells. Pulse-chase experiments showed that the gaps in the newly synthesized DNA from irradiated cells were filled in and that the DNA was joined and elongated in both cell types. These experiments demonstrate that both normal primary and malignantly transformed epidermal cells exhibit a postreplication gap-filling mechanism in response to UV irradiation. (46 refs)

78-3912 **Mutation to Ouabain-Resistance in Chinese Hamster Cells: Induction by Ethyl Methanesulphonate and Lack of Induction by Ionising Radiation.** (Eng) Thacker, J. (MRC Radiobiology Unit, Harwell, Didcot, Oxon OX11 0RD, England); Stephens, M. A.; Stretch, A. *Mutat Res* 51(2): 255-270; 1978.

The effect of ionizing radiation on the frequency of ouabain-resistant (OUAr) mutants in Chinese hamsters V79-4 cell cultures was examined. Ethyl methanesulfonate (EMS) was used as a positive control mutagen. In uncloned V79-4 cells, the spontaneous frequency of OUAr was approx 5×10^{-5}/viable cell. This frequency was initially reduced to approx 1×10^{-6} in 1 mM ouabain in freshly isolated clones or cultures started from a few cells. No increase in frequency of OUAr mutants was observed in cultures treated with γ-rays. Variation in radiation dose, ouabain concentration, posttreatment interval prior to selection, cell density in selective medium, and clonal state of the cells at the time of ouabain administration (in situ vs respreading technique) had no effect. Negative results were also observed with accelerated helium ions. In cultures treated with various concentrations of EMS, reproducibly large increases in the frequency of OUAr were observed. The relevant literature is reviewed, and the suggestion that ionizing radiation cannot induce OUAr mutants because of the severe genetic damage that it causes is discussed. (35 refs)

78-3913 **Xeroderma Pigmentosum Neurological Abnormalities Correlated with Colony-forming Ability after Ultraviolet Radiation.** (Eng) Andrews, A. D. (Dept Dermatology, Columbia Univ., Coll. Physicians and Surgeons, New York, NY, 10032); Barrett, S. F.; Robbins, J. H *Proc Natl Acad Sci USA* 75(4): 1984-1988; 1978.

The relationship between the neurological abnormalities o xeroderma pigmentosum (XP) and the sensitivity of cell from XP patients to UV radiation was examined in 24 X fibroblast strains. Sensitivity to UV radiation was studied i vitro by measuring the ability of each strain to divide an form colonies after irradiation. The most sensitive strain were derived from patients who had an early onset of neurological abnormalities, less sensitive strains were from patient with a later onset, and the most resistant strains were fro patients without neurological abnormalities. The UV sensitivities of strains from each member of a sibling pair wit XP were identical, indicating that UV sensitivity of X strains is determined by the patient's inherited DNA repai defect. The results suggest that effective DNA repair is required to maintain the functional integrity of the huma nervous system by preventing premature death of neurons (18 refs)

78-3914 **Inhibition and Enhancement of the Action o Mutagens by Chemical, Physical an Viral-modulating Factors (Meeting Abstract).** (Eng) Lo, L (Dept. Medical Genetics, Univ. British Columbia, Vancouver, British Columbia, Canada); Lam, P.; Stich, H. F. *Muta Res* 53(2): 221-222; 1978. (no refs)

78-3915 **The Use of Cytosine Arabinoside for Studyin the Rate and Extent of DNA Repair in Mammalian Cells Following Irradiation or Chemical Treatmen (Meeting Abstract).** (Eng) Preston, R. J. (Biology Div., Oa Ridge Natl. Lab., Oak Ridge, TN, 37830); Hiss, E. A. *Muta Res* 53(2): 250; 1978. (no refs)

78-3916 **Serologic Assay of DNA Base Damage. I 5-Hydroxymethyldeoxyuridine. A Radiatio Product of Thymidine.** (Eng) Lewis, H. L. (Lab. Nuclea Medicine and Radiation Biology, Univ. California, Los Angeles, CA, 90024); Muhleman, D. R.; Ward, J. F. *Radiat Re* 75(2): 305-316; 1978.

A serologic assay was developed for 5-hydroxymethyldeoxyuridine (5-HMUdR), an ionizing radiation product o thymidine (Thd). Antibodies were prepared to a bovin serum albumin conjugate of 5-hydroxymethyluridin (5-HMUR). Using a phage-neutralization assay, 0.1 nanomole of 5-HMUR could be detected. The antiserum cross-reacted with Thd but with no other naturally occurrin DNA component. There was cross-reaction with uridine 6-methyluracil, and the halogenated analogs of Thd. Interference by cross-reaction with Thd was eliminated by saturation of the assay with excess Thd. This also simulates the conditions for radiation studies, in which a small quantity of 5-HMUdR is determined in the presence of an excess of the parent compound, Thd. The assay was applied to the estimation of 5-HMUdR produced by irradiation of Thd in O_2. Irradiation at pH 14 increased the yield nine times over that obtained at neutral pH. Postirradiation heating at pH 9 or treatment with 10^{-3} ferrous ions, procedures that convert Thd methyl peroxides to 5-HMUdR, also increased product yield. Estimation of 5-HMUdR in DNA irradiated in O_2 gave results similar to those obtained with Thd. This yield is based on the assumption that binding of the antibody to the 5-hydroxymethyluracil moiety in DNA and to free 5-HMUR is similar. 5-MHUdR was detected at one nucleotide per 3 x 10^6 daltons of DNA. The results suggest that this serologic approach will be generally applicable to the detection and quantitation of a number of radiation products in DNA. (45 refs)

78-3917 **Radiation Damage to DNA in Aqueous Solution: A Comparison of the Responses of the Single-stranded Form with That of the Double-stranded Form.** (Eng) Ward, J. F. (Lab. Nuclear Medicine and Radiation Biology, Univ. California, Los Angeles, CA, 90024); Kuo, I. *Radiat Res* 75(2): 278-285; 1978.

The responses of single-stranded (ss) and double-stranded (ds) DNA to radiation in aqueous soln were compared. Comparison of the absorption spectra of transient DNA-OH radicals immediately after pulse radiolysis indicated that the spectrum of the transient DNA-OH radical formed from ssDNA has a higher absorbance than that of the dsDNA-OH radical. After 400 μsec in the presence of oxygen, there was little change in the spectrum from dsDNA, but an appreciable decay was seen in the spectrum from ssDNA. This decay was complete in 400 μsec and did not occur in the absence of oxygen. These results suggest that the dsDNA-OH transient does not react with molecular oxygen but that ssDNA-OH radical does. The yield of strand breaks in neutral soln was 2.5 times as high for dsDNA as for ssDNA suggesting greater relative sugar damage in dsDNA. The number of alkali-produced strand breaks was higher than that seen in neutral solns for both DNA's but those for ssDNA were almost double those seen with dsDNA. The higher yield of alkali-produced breaks indicates more base damage. In the presence of oxygen, the yield of free thymine was almost the same in both DNA's; this yield can be correlated with sugar damage. The yields of damaged bases were much lower in dsDNA than in ssDNA. It is hypothesized that the nucleic acid bases are protected inside the double helix against the reactions of OH free radicals. Thus, in assessing damage to native DNA, radiation damage to deoxynucleotides does not provide an accurate model. (19 refs)

78-3918 **Spontaneous and Radiation-induced Benign Tumors in Parabiont Rats.** (Eng) Warren, S. (Cancer Res. Inst., New England Deaconess Hosp., Boston, MA, 02215); Gates, O.; Brown, C. E.; Chute, R. N.; Porter, M. W. *JAMA* 75(1): 98-107; 1978.

The incidence of spontaneous benign tumors in NEDH rats, as well as of those induced by parabiosis and radiation, is reported. NEDH rats of the same age and sex were parabiosed at about 35 days of age. At 110 days of age, the right-hand members were irradiated with a single whole-body exposure of 1,000 R of 250-kilovolt peak x-rays. The left-hand members were shielded to ensure survival of their partners from the otherwise fatal x-ray dose. There were three series of controls: single untreated rats; parabiosed, untreated rats; and the shielded partners of the irradiated rats. The radiation produced high incidence rates of benign tumors in several radioresponsive organs: ovary, 49.7%; adrenal medulla (males, 23.9%; females, 15.2); mammary tissue (female 19.6%); islands of Langerhans (males, 15.3%); liver (cholangiomas: males, 7.4%; females, 13.8%). Both hormonal imbalance and radiation effects appear to be involved. Endometrial polyps, although more frequent in irradiated than in shielded partners, probably resulted from hormonal imbalance. In females, the incidence of pituitary adenomas was four times as high in the shielded partners (16%) as in the irradiated partners (4.2%), probably the result of sterilization of the ovaries in the latter. Parabiosis decreased the incidence of pheochromocytoma, but irradiation of a partner increased it. Mammary tumors occurred an av of 200 days earlier in irradiated rats than in their unirradiated controls. Among the many benign lesions studied, only a few showed changes indicating transition to a malignancy. (21 refs)

78-3919 **Dose-Incidence Variations of Reticulum Cell Sarcoma in Mice with Irradiated Bone Marrow.** (Eng) Covelli, V. (Lab. Radiation Pathology, Centro di Studi Nucleari della Casaccia, Comitato Nazionale per l'Energia Nucleare, Casella Postale 2400, 00100 Rome, Italy); Ballardin, E.; Di Majo, V.; Bassani, B.; Metalli, P. *J Natl Cancer Inst* 61(4): 1131-1133; 1978.

The incidence of reticulum cell sarcoma (RCS) in irradiated and limb-shielded [C57BL/Cne(female) x C3H/Cne(male)]-F1 male mice as a function of radiation dose to the shielded marrow was determined. When used, the shields were kept in place over one or both hind legs for only part of the time required to irradiate the rest of the body. The av final incidence of RCS in untreated control mice was 57%, and it was not significantly changed by single acute whole-body doses of x-rays up to 400 rads. Higher doses sharply decreased this incidence to very low levels. In a syngeneic chimera system, however, irradiation (400 rads) of bone marrow prior to transplantation significantly increased the frequency and rate of RCS relative to transplantation of unirradiated marrow. An endogenous repopulating system was tested; marrow was irradiated in situ by a limb-shielding technique. The results indicated a biphasic dose-incidence curve with a peak at 500 rads. The rising part of the curve agreed with and extended the conclusion from the exogenous system, whereas the descending portion at higher doses paralleled the trend observedin whole-body x-irradiated animals. Finally, the irradiation of two hind legs resulted in a higher frequency of RCS than did irradiation of only one leg at the same dose levels. The results strongly indicated that the frequency of radiation-induced tumors in marrow-irradiated mice is correlated with the mass and, hence, with the numbers of cells at risk of being transformed by irradiation. (9 refs)

78-3920 **Decline of Natural Killer Cell Activity in Sublethally Irradiated Mice.** (Eng) Hochman, P. S. (Dept. Pathology, State Univ. New York, Buffalo, NY, 14214); Cudkowicz, G.; Dausset, J. *J Natl Cancer Inst* 61(1): 265-268; 1978.

Spleen cells of (C57BL/6 x C3H/He)F$_1$ mice were assayed for natural killer (NK) cell activity against YAC-1 and FBL-3 lymphoma targets at intervals after total-body exposure to a high sublethal dose of ^{137}Cs or ^{60}Co x-rays. NK cell activity did not decline for the first 12 days, but there was a marked loss of cellularity in the spleen (80%-90%). During the subsequent period of rapid regeneration of splenic cellularity, NK cell activity decreased sharply, so that the values of specific lysis were $< 10\%$. The earliest drop of NK cell activity was detected on day 14; activity became minimal on days 17 and 19. During the fourth and fifth weeks, cellularity was 60%-90% of controls and NK cell activity was low but tendency toward recovery was noted. Near normal levels of NK activity were reached 6-8 wk after irradiation. Suppressor cells were detectable during the period of lowest NK cell activity, and they may have been responsible for the delayed and slow recovery. It is concluded that (1) mature effectors of natural cytotoxicity are relatively radioresistant renewable cells with a life-span of 2 wk whose progenitors are radiosensitive cells and (2) the kinetics of decline and recovery of NK cell activity may be influenced by suppressor cells. (12 refs)

78-3921 **Effect of Ovariectomy on X-Ray Carcinogenesis in Rats.** (Eng) Takizawa, S. (Dept. Cancer Res., Res. Inst. Nuclear Medicine and Biology, Hiroshima Univ., Kasumi 1-2-3, Hiroshima 734, Japan); Naito, Y.; Watanabe, H.; Hirose, F. *Gann* 69(3): 353-360; 1978.

Tumor induction by fractionated whole-body x-radiation (400 rads) was studied in ovariectomized (OV-X), OV-X and ovary-grafted (OV-X,OV-G), and sham OV-X (S-OV-X) Sprague-Dawley rats. Ovariectomy was performed 3 days before the last (4th) radiation treatment. OV-X rats gained more body wt and responded more quickly (but transiently) in recovery of WBC levels after the last x-irradiation than the other rats. A total of 26 tumors developed in 21/47 OV-X rats, 11 tumors in 6 /13 OV-X,OV-G rats, and 44 tumors in 25/29 S-OV-X rats during the observation period (up to 64 wk after the starting of x-irradiation). In the latter two groups, 80% of the tumors were of mammary gland origin. In contrast, 61.1% of tumors in the OV-X rats were derived from sc mesenchymal tissue and hematopoietic tissue. This indicates that some forms of mesenchymal tumors, including leukemia, may be under the suppressive influence of female sex hormones. (12 refs)

78-3922 **Ovarian Tumor Types and Their Incidence in Intact Mice Following Whole-Body Exposure to Ionizing Radiation.** (Eng) Clapp, N. K. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830). *Radiat Res* 74(3): 405-414; 1978.

In a large-scale experiment, 3,135 8-wk-old RF/Un mice were exposed to 0-400 rads of whole-body radiation with 60-million electron volt protons or 300-kilovolt peak x-rays in single doses at a rate of 80-100 rads/min, and the incidence and types of ovarian tumors produced were determined. Since there were only minor differences in effect between the two treatments, both groups were combined by dose for analysis of the data. Ovarian tumors developed in 3.8% of the untreated mice and 50%-60% of those given 50-100 rads; the incidence declined gradually with 100-400 rads. Tumor cell types were identified histologically in 2,400 mice. There were 479 single cell tumors [309 tubular adenomas (TA), 85 granulosa cell (GC) tumors, 60 luteomas (L), 17 hemangiomas, 6 adenocarcinomas, 2 fibrosarcomas] and 467 mixed cell tumors (123 bilateral mixed tumors, 112 of which were L; 289 L in one ovary, 42 GC + L and/or TA; 13 miscellaneous types). At 0-100 rads, the relative proportions of mixed cell tumors increased and single cell tumors decreased; they were about equal at 100-400 rads. Approx 90% of the ovarian tumors at 50 rads contained TA elements; this decreased to 70% at 400 rads. L increased to 40% at 50 rads and 60% at 100 rads, but showed no dose effect at 100-400 rads. GC tumors showed no dose effect, remaining at an incidence of 15%-20%. At 50 rads, TA were most common, L were intermediate, and GC tumors were lowest in occurrence. The prevalence of tumor cell types suggests a relative sensitivity of ovarian tissues to radiation-induced tumorigenesis after whole-body ionizing radiation. (14 refs)

78-3923 **Role of Age in Tumorigenesis in Irradiated Animals.** (Rus) Pavlenko-Mikhailov, Iu. N. (No affiliation given); Stre'tsova, V. N.; Strashnenko, S. I.; Oshchepko, A. B. *Radiobiologiia* 18(2): 218-222; 1978.

The association between age and the tumorigenic effect of radiation was studied in random-bred albino rats. Newborn rats were divided into five groups: Groups 1-4 (treated at 1, 2, 4 wk and at 4 mo of age, respectively) were given a single dose of 200 R radiation, and Group 5 served as controls. Irradiation significantly increased the frequency of ovarian, pituitary, and mammary gland tumors. Ovarian tumors were detected only in Groups 1-3: 10/18, 11/30, and 11/28 rats, respectively, on day 800 postirradiation. On day 540, pituitary tumors were found in 5/18 rats in Group 1, 5/30 rats in Group 2, 6/28 rats in Group 3, and 36/50 rats in Group 4, compared with 1/30 rats in Group 5. The incidence of mammary gland tumors was significantly greater in Group 4 (38/50, vs 5/18, 7/30, and 8/28 in Groups 1, 2 and 3, respectively). The incidence in Group 5 was 4/20. The latent period of mammary gland tumors in Groups 1-4 was decreased by 500, 470, 380, and 120 days, respectively. (11 refs)

78-3924 Characteristic Features of the Development of Radiation-induced Tumors of the Stomach and Intestine. (Rus) Lebedeva, G. A. (No affiliation given). *Vopr Onkol* 24(7): 73-77; 1978.

The carcinogenic effect of ionizing radiation was studied in dogs and rats. Animals were divided into three groups: Group 1 consisted of 52 dogs subjected to mixed gamma-neutron radiation at doses ranging from 272 to 2,351 biological equivalent of roentgen (ber). Group 2 consisted of 25 dogs subjected to sc implantation of the alpha-emitter ^{210}Po (2.5 μCi/kg). Group 3 consisted of 250 rats who received the beta-emitter ^{144}Ce (9, 12, 15, and 18 μCi/g) intragastrically. Dogs were sacrificed 11.5 mo to 11.4 yr later, rats 1-26 mo later. The av latent period of tumor development in Groups 1, 2, and 3 was 7.4 yr, 9.2 yr, and 11.0 mo, respectively. Dogs in Groups 1, 2, and 3 was 7.4 yr, 9.2 yr, and 11.0 mo, respectively. Dogs in Groups 1 and 2 had predominantly benign tumors (100% and 93.3%, respectively), but 78.3% of the rats developed malignant tumors. Approx 50% of the malignant tumors were located in the stomach and intestine. (11 refs)

78-3925 Gamma-Ray-induced Dominant Mutations That Cause Skeletal Abnormalities in Mice. II. Description of Proved Mutations. (Eng) Selby, P. B. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Selby, P. R. *Mutat Res* 51(2): 199-236; 1978.

Breeding tests were used to determine if γ-radiation-induced dominant skeletal mutations in male 101 strain mice can be transmitted. Spermatogonia irradiated with 100 R + 500 R γ-rays, the mice were bred with C3H females, and the F1 males were outcrossed with three (101 x C3H)F1 females. The F1 males were killed, and their skeletons were cleared and examined for abnormalities. If a male had one or more unusual skeletal abnormalities, his progeny (FOP) were saved and approx half of them were examined for abnormalities. If the FOP clearly had abnormalities transmitted from the sire, they were further outcrossed and their offspring examined for anomalies. Thirty-one dominant skeletal mutations were observed, each of which is described in detail. The data provide the basis for determining which mutations cause effects that would, if they occurred in humans, cause a serious handicap. Most of the mutations resulted in multiple abnormalities. They exhibited low penetrance for many of their effects. Many dominant skeletal mutations produced a general stunting of body growth. Externally visible effects found in some heterozygotes for a few mutations included hydrocephalus, circling behavior, increased nervous activity, gray color coat, webbing of digits, and small size. The results indicate that some of the mutations may be reciprocal translocations; however, cytological testing of most of the mutant lines gave no indication of chromosome aberrations. (14 refs)

78-3926 Induction of Hepatocellular Tumor by X-Ray Irradiation at Perinatal Stage of Mice. (Eng) Sasaki, S. (Div. Radiation Hazards, Natl. Inst. Radiological Sciences, Anagawa 4-9-1, Chiba 280, Japan); Kasuga, T.; Sato, F.; Kawashima, N. *Gann* 69(3): 451-452; 1978.

The incidence of hepatocellular carcinoma after x-ray irradiation was determined in the F_1 hybrids of C57BL/6 x WHT/Ht (B6WF$_1$) mice. The mice were grouped as follows: Group 1, unirradiated controls; Group 2, irradiated in utero at 17 days' postcoitum with 150 or 300 R; Group 3, irradiated within 24 hr after parturition with 400 R; Group 4, females only, irradiated at 5 wk of age with 400 R. The incidence of hepatocellular carcinoma was markedly enhanced by irradiation, especially in Group 3; the incidence in males and females was 68% and 44%, respectively, vs 7% and 1% incidences in Group 1. Age at death with hepatocellular tumor was 612 days in Group 3 males, (vs 877 days in Group 1, 793 and 623 days in Group 2) and 626 days in Group 2 females (vs 812 days in Group 1, 927 and 756 days in Group 2). Perinatal female mice were more susceptible than 5-wk-old females (14% incidence) to the x-ray-induced tumors. The high susceptibility of perinatal mice to x-ray-induced hepatocellular tumorigenesis may be related to the high frequency of mitosis at and/or after x-ray irradiation. (5 refs)

78-3927 Effects of Fast Neutrons on Rabbits--I. Comparison of Pathologic Effects of Fractionated Neutron and Photon Exposures of the Head. (Eng) Bradley, E. W. (708 Ross Hall, 2300 Eye St., N. W., Washington, DC, 20037); Zook, B. C.; Casarett, G. W.; Bondelid, R. O.; Maier, J. G.; Rogers, C. C. *Int J Radiat Oncol Biol Phys* 2(11/12): 1133-1139; 1977.

Adult New Zealand white rabbits received one of four head irradiation doses of neutrons [mean energy 15 million electron volts; 1,680-6,720 rads] or photons (4,800-19,200 rad). Each of the photon dose levels was 2.86 rads larger than the corresponding neutron dose level. The fast neutrons were produced at the Naval Research Cyclotron in Washington, DC, by bombarding a thick beryllium target with 35-MeV deuterons. The photon irradiation was produced by a 4-megavolt linear accelerator at the George Washington Univ. Medical Center. Control rabbits received no irradiation. The neutron and photon rabbits were irradiated twice weekly for 6 wk, the fractionation schedule used for treatment of advanced malignancies by the Middle Atlantic Neutron Therapy Association at the time of initiation of this experiment. The onset and severity of skin lesions and mucosal reactions in irradiated regions appeared to be dose-dependent and more severe in photon-irradiated rabbits. Death was commonly caused by complications of mucosal reactions. Three of the five rabbits that had received the lowest neutron dose (1,680 rads), a dose commonly administered to neutron-irradiated patients, developed invasive and metastasizing osteosarcomas within the irradiated field < 1 yr after the irradiation was completed. (34 refs)

78-3928 **Second Neoplasms Following Megavoltage Radiation in a Pediatric Population.** (Eng) Haselow, R. E. (Dept. Therapeutic Radiology, Box 494, Univ. Minnesota Hosp., Minneapolis, MN, 55455); Nesbit, M.; Dehner, L. P.; Khan, F. M.; McHugh, R.; Levitt, S. H. *Cancer* 42(3): 1185-1191; 1978.

The long-term oncogenic effects of exposure of children to megavoltage treatment with cobalt-60 were reviewed based on the records of 88 patients followed for 6-22 yr. Criteria for inclusion in the study were age < 16 yr at the time of treatment, min of 10 yr survival after inital treatment or follow-up until second neoplasm (1 case), and absence of diseases with known susceptibility to cancer. Patients could have been treated additionally with orthovoltage radiation, and the primary lesion did not have to be malignant. During follow-up period (av, 14 yr) seven second neoplasms were discovered, five benign and two malignant. Five of these tumors were not related to the prior radiation. Both radiation-induced tumors(1 benign, 1 malignant) were associated with low doses (< 1,500 rads) and one was without significant morbidity. The benign tumor was a chondromatous hamartoma of the lung. The malignant tumor was an ependymoma of the fourth ventricle in a patient treated 15 yr previously with 500-600 rads to the fourth ventricle for histiocytosis. This patient had also received long-term treatment with multiagent chemotherapy. (49 refs)

78-3929 **Hyperparathyroidism after Radiotherapy.** (Eng) Erkocak, E. U. (Dept. Surgery, Cukurova Univ. Medical Faculty, Adana, Turkey); Taylor, S. *Br Med J* 2(6133): 327-328; 1978.

A 66-yr-old man who had undergone a 6-mo course of external radiation therapy for tuberculous lymph nodes at age 5 presented with hyperparathyroidism. Both parathyroid glands on the irradiated side of the neck showed hyperplasia. There was also a neuroma and a nodular goiter in this area, both of which are recognized as consequences of radiation. (5 refs)

78-3930 **Cancer in Parents of Children with Leukemia (Letter to Editor).** (Eng) Marchetto, D. J. (Sidney Farber Cancer Inst., Boston, MA, 02115); Li, F. P.; Meadows, A. T. *J Pediatr* 93(3): 537; 1978.

A report of irradiation-associated thyroid carcinomas in parents of children with acute leukemia prompted the investigation of 1,274 parents (906 mothers, 368 fathers) of such children. None of the 1,274 had thyroid carcinoma, and the incidence of other neoplasms was not thought to be excessive (0.8% vs 0.7% expected). These findings suggest that thyroid carcinoma of any cause is rare among parents of children with acute leukemia. (7 refs)

78-3931 **Radiation-induced Hypoplasia and Carcinoma of the Breast.** (Eng) Kleinfeld, G. (No affiliation given). *Breast* 4(1): 25-26; 1978.

Two cases of mammary hypoplasia caused by therapeutic irradiation in childhood are described. One patient was a 34-yr-old woman who had been treated for a hemangioma of the right breast at age 3 yr by applications of radium. The second, a 34-yr-old woman who had received external radiation at age 3 yr for bursitis of the shoulder, was also found to have intraductal carcinoma at surgery. It is concluded that carcinogenicity of the breast is related to concentrated exposure to radiation. This exposure occurs with therapeutic, not diagnostic, radiation dosages. Exposure of young women and prepubertal girls appears to be more dangerous than exposure of more mature women. There also appears to be a risk of inducing supervening breast cancer in premenopausal women treated for breast cancer by whole-breast irradiation without mastectomy. (6 refs)

78-3932 **Thorotrast Carcinoma of the Lung that Developed after a Bullet Wound and Thorotrast Application.** (Eng) Buchholz, A. (Institut fur Pathologie, Bezirkskrankenhaus/Poliklinik, Pfaffenstrass 24, DDR-20 Neubrandenburg, E. Germany). *Z Erkr Atmungsorgane* 150(1): 76-89; 1978.

A 50-yr-old man developed a bronchogenic carcinoma at the site of a scar from a bullet wound he received in 1945, 27 yr before his death. Histological examination disclosed considerable deposits of thorotrast in the carcinoma and scar tissue. It is probable that, in connection with treatment of the wound, bronchography with the use of thorotrast or preparation of a fistula were performed. All available literature cases on the development of carcinoma after a pulmonary bullet wound as well as all cases of pulmonary carcinoma development after thorotrast incorporation were collected, sorted, and tabulated. Theories concerning the etiology and pathogenesis of these tumors are presented. (62 refs)

78-3933 **Tissue Dose in Thorotrast Patients.** (Eng) Kaul, A. (Klinikum Steglitz, Freien Universitat, Berlin, W. Germany); Noffz, W. *Health Phys* 35(1): 113-121; 1978.

Absorbed α-ray doses to the liver, spleen, red marrow, lungs, and kidneys and to various parts of bone tissue were calculated for long-term burdens of iv-injected Thorotrast (TT). The calculations, performed for injection of 10, 30, 50, or 100 ml of colloidal thorium dioxide ($^{232}ThO_2$), were based upon best estimates of ^{232}Th tissue distribution and steady-state activity ratios between the subsequent daughters. Correcting for α-particle self-absorption within TT aggregates (up to 100 μm across, giving rise to substantial self-absorption), the mean α-ray dose to a standard 70-kg human at 30 yr after the injection of 25 ml TT is 750 rads to the liver, 2,100 rads to the spleen, 270 rads to the red marrow, 60-620 rads to the lungs and 13 rads to the kidneys. Dose rates to bone tissue were estimated by applying a model on alkaline earth metabolism to the continuous translocation of Th daughters to bone and to the formation of Th daughters by decay within bone tissue. The av dose to calcified bone from translocated radium-224 and its daughters is 18 rads at 30 yr after the injection of 25 ml TT. Considering a previously calculated risk coefficient of 0.9%-1.7% bone sarcomas/100 rads of av skeletal dose from ^{224}Ra and its daughters, the induction of 1.6-3.1 bone sarcomas per 1,000 TT patients is predicted. (22 refs)

78-3934 **Endosteal Dose to Thorotrast Patients.** (Eng) Mays, C. W. (Radiobiology Lab., Bldg. 522, Univ. Utah, Salt Lake City, UT, 84112). *Health Phys* 35(1): 123-125; 1978.

The endosteal dose rate was calculated for a typical iv injection of 25 ml of Thorotrast (TT) (0.55-0.65 μCi thorium-232) into a 70-kg human with 5,000 g of calcified bone, 1,500 g of red marrow, and 125 g endosteal tissue. The dose rate to the endosteum, 0-10 μg from bone surfaces, was estimated to be 16 rads/yr, 7 rads/yr from radium-224, ^{228}Th, and ^{228}Ra translocated from Thorotrast to calcified bone and 9 rad/yr from Thorotrast on bone surfaces and in red marrow. These figures were obtained by multiplying the av organ dose rate by the previously tabulated ratio of endosteal dose to av dose. Punctate sources of Thorotrast irradiate fewer bone cells but kill a higher proportion of those that are irradiated, compared with the more uniform irradiation from calcified bone. It is thus possible that the endosteal dose from Thorotrast is less effective in osteosarcoma induction than that from ^{224}Ra. The endosteal dose rate to a typical Thorotrast patient would then be equivalent to an endosteal dose rate of 7-16 rads/yr from protracted ^{224}Ra. (8 refs)

78-3935 **Lymphoid Tumours and Leukemia Induced in Mice by Bone-seeking Radionuclides.** (Eng) Loutit, J. F. (MRC Radiobiology Unit, Harwell, Didcot, Oxon, England); Carr, T. E. *Int J Radiat Biol* 33(3): 245-263; 1978.

Harwell stock CBA and C3H mice and their F_1 hybrids were inoculated ip with single carcinogenic doses of ^{90}Sr (7, 13, or 20 μCi/mouse), ^{226}Ra [50, 150, or 500 nanocuries (nCi)/mouse], or ^{239}Pu (2, 4, 10, 30, or 100 nCi/mouse) in soln and examined for the development of lymphoid tumors and leukemia. Soluble ^{90}Sr and monomeric ^{239}Pu induced generalized lymphomatosis in laboratory mice. Leukemogenesis due to soluble ^{226}Ra was more uncertain. Clinical expression was variable, but as a rule, the disease was a lymphosarcoma with hematogenous (leukemic) spread. The cell type was lymphoblastic of undifferentiated null form. The av doses of α or β radiation that accumulated in the bone marrow at the time of diagnosis were usually $>$2,500 rads, but if the cases occurring after Ra or low activities of Pu are accepted as being induced, doses of α radiation could have been as low as 300-1,500 rads. Chimeric mice rarely exhibited any lymphoma, general or local, following treatment. Abdominal lymphomas were not numerically increased by these radionuclides, although some may have been prematurely induced. (35 refs)

78-3936 **Radiation Leukaemogenesis: Is Virus Really Necessary?** (Eng) Loutit, J. F. (M.R.C. Radiobiology Unit, Harwell, Didcot, OX11 ORD, England); Ash, P. J. *Br J Cancer* 38(1): 24-33; 1978.

Generalized nonthymic lymphosarcomas from mice injected with ^{90}Sr, ^{239}Pu, or ^{226}Ra were maintained in unirradiated compatible mice and used as a source of tumor-associated antigen to determine whether repeated administration of this antigen would lead to progressive resistance to the tumor. If the tumor-associated antigens are virally determined, they should evoke a protective immunity. Subthreshold doses of living syngeneic tumor, large doses of living allogeneic tumor, and large doses of killed syngeneic tumor did not protect compatible mice from the development of lymphosarcomas. This suggests that the viruses seen electron microscopically in these tumors were not the etiological agents. The ultrastructure of the tumors and the characteristics of the viruses (mainly A-type) they contained are also presented. (24 refs)

78-3937 **Dose to Endosteal Cells and Relative Distribution Factors for Radium-224 and Plutonium-239 Compared to Radium-226.** (Eng) Marshall, J. H. (Center Human Radiobiology, Argonne Natl. Lab., Argonne, IL, 60439); Groer, P. G.; Schlenker, R. A. *Health Phys* 35(1): 91-101; 1978.

Information forming the basis for calculations of the dose to the endosteal cells from iv injections of radium-224 in adult humans is reviewed, and relative distribution factors (RDF's) for ^{224}Ra, and plutonium-239 relative to ^{226}Ra are derived. A model of alkaline earth metabolism in adult humans predicts that 10% of injected ^{224}Ra atoms decay on bone surface, 1.5% in bone volume. New measurements of the total surface/volume ratio of bone from 10 human skeletons gave a preliminary value of 50 cm^2/cm^3. RDF's were determined by calculating the ratio of the endosteal doses for equal av doses to bone for both ^{224}Ra and ^{239}Pu relative to ^{226}Ra (from a volume source). These factors predict the relative toxicity of α-emitting radionuclides in humans relative to ^{226}Ra on the assumption that the dose to endosteal cells is the causative factor. The value of RDF (^{224}Ra/^{226}Ra) was 20 and that of RDF (^{239}Pu/^{226}Ra) was 28 for a surface source of Pu and 0.96 for a vol source. The RDF's for α-emitters relative to ^{226}Ra were almost independent of distance for cell targets within 30 μm of the bone surface. Taking the fraction of injected ^{224}Ra atoms that decay in bone volume or on bone surface as 11.5%, assuming 100% retention of thoron and its daughters at bone surface, and using previously reported integrations, it was estimated that an iv injection of 1 μCi ^{224}Ra in a 70-kg standard human with 5 kg of bone results in an av dose to endosteal cells 0-10 μm from bone surfaces of 1.46 rads, slightly less than the dose of 1.77 rads calculated in another study. (25 refs)

78-3938 **Post-irradiation Sarcoma of the Clavicle: A Report of Two Patients.** (Eng) Evans, M. J. (Orthopaedic Dept., Middlesex Hosp., London, England); Hughes, S. P. *Clin Oncol* 4(2): 131-138; 1978.

A 61-yr-old woman and a 27-yr-old man developed a sarcoma of the clavicle 9 and 10 yr, respectively, after receiving radiation to the same area. Radiation was initiated following mastectomy for a spheroidal cell carcinoma in the woman and as treatment for a reticulum cell sarcoma of the neck in man. Total radiation doses were 4,740 and 5,000 rads, respectively. Four similar cases in the literature are reviewed. (14 refs.)

78-3939 **Pulmonary Connective Tissue Modifications Induced by Internal α Irradiation. I. Effect of Time and Dose on Alterations Following Inhalation of Plutonium-239 Dioxide Aerosol in Rat.** (Eng) Metivier, H. (Commissariat a l'Energie Atomique, Departement de Protection, Laboratoire de Toxicologie Experimentale, Boite Postale 561, 92542 Montrouge Cedex, France); Masse, R.; Legendre, N.; Lafuma, J. *Radiat Res* 75(2): 385-396; 1978.

Female Wistar rats were exposed by inhalation to an aerosol of relatively insoluble $^{239}PuO_2$ to quantitate the relationship between pulmonary radiation dose and dose rate and induced fibrosis. Lung wt, whole proteins, collagen, and uronic acids were determined as functions of dose and time. Total pulmonary collagen was increased up to 200% of that in control animals at 200 days after exposure at an α radiation dose to the lung of 100-10,000 rads. At 400 days, however, the total pulmonary collagen was similar to that of controls. The same evolution was observed with uronic acids. This biphasic effect was specific, since it was not observed for total proteins in the lung. Modifications of the fresh lung/dry lung ratio or significant changes in blood gases were not observed. Scars appeared and foci of the usual interstitial pneumonia were observed around trapped particles 100 days after inhalation. In animals given doses of 3,000-10,000 rads, the lesions consisted of small focal areas scattered in the lung. Most of the connective tissue deposits in these areas were due to strongly argyrophilic fibers. In the group followed 400 days after inhalation, there was no decrease of this scarring effect. Metaplasia and adenomatosis were constant at doses > 1,000 rads, and some cancers were seen. It was concluded that the decrease in connective tissue components observed with biochemical methods at later times correlates only with an evenly distributed tissue alteration; ie, the strongly argyrophilic fibers. 78-3940 **A Routine Procedure for the Determination of Trace Amounts of Plutonium in Urine.** (Eng) Veselsky, J. C. (International Atomic Energy Agency, Lab. Seibersdorf, A-2444 Siebersdorf, Austria). *Mikrochim Acta* 1(1/2): 79-88; 1978.

A method for determining trace amounts of plutonium in urine was developed to monitor personnel involved in nuclear energy production. The method allows large samples to be processed without time-consuming evaporation steps and no unusual or expensive reagents are required. The chemical recovery is ≥90%; the detection limit is 40 femtocuries ^{239}Pu/liter. (40 refs)

78-3941 **Relationship Between Physicochemical Form of Plutonium and Its Behavior in Tissues and in the Mouse Reticuloendothelial System. I. Distribution of Monomeric and Polymeric Pu after Sc Injection in Mice.** (Jpn) Kashima, M. (Div. Radiation Hazards, Natl. Inst. Radiological Sciences, 9-1, Anagawa 4 chome, Chiba, 280, Japan); Joshima, H.; Matsuoka, O. *Nippon Acta Radiol* 38(1): 65-80; 1978.

The distribution of plutonium was studied in a section of human skin that was accidentally punctured by a needle contaminated with $^{239}Pu(NO_3)_4$ and in mice given sc injections of monomeric or polymeric Pu. The human skin was surgically removed 2 hr after the accident and subjected to autoradiography. A total of 24 nanoCi of ^{239}Pu were detected. Although most of the alpha tracks in the malpighian layer and cornium of the skin were single tracks, several star tracks and clusters of tracks were also observed. The polymerization, translocation, and deposition of Pu were studied in mice following sc injection of fresh monomeric Pu soln at pH 1, 4, 7.2, and 13; monomeric Pu soln stored for 348 days at pH 7.2; and pure polymeric Pu. The whole-body distribution of monomeric Pu at pH 4 and 7.2 and of stocked Pu showed a similar pattern. However, there was a difference in the diffusible Pu pattern at the injection site between monomeric Pu at pH 4 or 7.2, and that at pH 1 or 13 and polymeric Pu. The former was spread throughout the sc tissue, but the latter was not. Several star tracks were observed at the site of monomeric Pu injection; this may have been the result of polymerization of monomeric Pu in the skin. Although low Pu levels were found in the blood 3 hr after injection, Pu, especially the polymeric form, was most likely to be removed from the skin by way of the lymphatics. Translocation of Pu to the bone, liver, spleen, bone marrow and lymph nodes was observed by 3 hr; distribution was uniform in the bone marrow only. In the liver, the highest concentrations were found in the zone surrounding the central vein. (32 refs)

78-3942 **Local Dose to Lung Tissue from Inhaled $^{238}PuO_2$ Particles.** (Eng) Diel, J. H. (Inhalation Toxicology Res. Inst., Lovelace Biomedical and Environmental Res. Inst., P.O. Box 5890, Albuquerque, NM, 87115). *Radiat Res* 75(2): 348-372; 1978.

A new method for computing local dose to tissue from an α-emitting particle in deep lung is described. Syrian hamsters were exposed by inhalation to 0.2-μm real diameter $^{238}PuO_2$ particles and then sacrificed 8-35 days later. The trachea was cannulated; the lungs were inflated and fixed in situ, excised, paraffin-embedded, and sectioned at 5 μm thickness; and autoradiographs were prepared. Seven particles from three animals were chosen at random from these autoradiographs, and the location of the particle and the configuration of the tissue surrounding the particle were analyzed by a computer. The local dose rate and fraction of α-particles that penetrate to or pass through tissue at a given distance from the source were computed. The local dose rate was used to compute the effect of this radiation pattern based on four empirical formulas. The av effects obtained were similar to those calculated assuming a structureless lung of uniform density (0.2 g/cm^3), but they were different from calculated effects based on uniform dose over the irradiated region. The relationship between dose rate and distance from an α-emitting particle in deep lung was virtually independent of the location of that particle. Under the dose effect assumptions used, the results indicate that there is an inverse or possibly constant relationship between the activity contained in a $^{238}PuO_2$ particle deposited in lung and its effectiveness in producing tumors. They also indicate that there is a direct relationship between cell turnover time and tumor production. (34 refs)

78-3943 **Foreign-Body Tumorigenesis in Mice: DNA Synthesis in Surface-attached Cells During Preneoplasia.** (Eng) Thomassen, M. J. (Dept. Pediatrics, Case Western Reserve Univ., Cleveland, OH, 44106); Buoen, L. C.; Brand, I.; Brand, K. G. *J Natl Cancer Inst* 61(2): 359-363; 1978.

DNA synthesis throughout the stages of foreign body (FB) tumorigenesis was investigated to provide insight into the role of macrophages in the development of neoplasia. Four unplasticized vinyl chloride-vinyl acetate copolymer films (15 x 22 mm) were implanted sc into the flanks of (CBA/H x CBA/H-T6)F_1 mice. The animals were pulsed with ^{3}H-thymidine at various times during the next 15 mo. DNA synthesis occurred consistently in the film-attached cells, predominantly macrophages, throughout the preneoplastic phase in both male and female mice. The labeling rate was calculated to be 5-15 cells/1,000, the cell turnover rate to be 1.5%-4.5%/day, and the mitotic rate to be <3 cells/10,000. Giant cells with <10 nuclei were labeled synchronously and asynchronously. No DNA synthesis was detected in giant cells with >10 nuclei. The results show that the macrophages were not dormant with respect to DNA synthesis. (16 refs)

78-3944 **Unwinding-like Activity Associated with Avian Retrovirus RNA-directed DNA Polymerase.** (Eng) Collett, M. S. (Dept. Pathology, Univ. Colorado, Medical Sch., Denver, CO, 80262); Leis, J. P.; Smith, M. S.; Faras, A. J. *J Virol* 26(2): 498-509; 1978.

An activity associated with purified preparations of avian retrovirus reverse transcriptase that is capable of dissociating hydrogen-bonded regions from duplex nucleic acid molecules is described. This "unwindinglike" activity appears specific, affecting RNA-DNA and DNA-DNA duplex molecules but not RNA-RNA duplexes. It can remove a portion of the hydrogen bonds from double-stranded structures, but it cannot separate complementary strands completely. The unwindinglike activity was sensitive to temperature and monovalent and divalent cation concentrations. It could also remove a specific large oligonucleotide from the 5′ end of the viral genome subsequent to RNase H hydrolysis of viral RNA complexed to DNA present at that terminus. It is speculated that this activity may be involved in the removal of RNA oligoribonucleotides from RNA-DNA hybrid intermediates by the viral RNase H activity during proviral DNA synthesis. (27 refs)

78-3945 **Neoplasms Resembling Lymphoid Leukosis in Chicken Flocks Free of Infection with Exogenous Lymphoid Leukosis Virus.** (Eng) Crittenden, L. B. (Regional Poultry Res. Lab., U.S.D.A., ARS, East Lansing, MI); Neiman, P. E.; Okazaki, W.; Sharma, J. M.; Witter, R. L. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York Elsevier/North Holland Biomedical Press): 503 pp.; 456-457; 1978.

An attempt was made to determine the etiologic agent involved in 12 cases of apparent lymphoid leukosis (LL) that occurred spontaneously in an inbred line of chickens that consistently produces the endogenous Rous-associated virus RAV-O. The LL occurred in sublines of line 7 or in F_1 hybrids of line 7. In 8/12 birds, the bursa of fabricius was grossly neoplastic. Tests excluded LL virus, Marek's disease virus, and reticuloendotheliosis virus as etiologic agents. DNA from these tumors hybridized with RNA extracted from RAV-O, but the reaction kinetics were not different from those observed with normal chicken cell DNA. A subgroup E leukosis virus isolated from infected chickens was injected into recipient birds, but no lymphoid tumors were induced by >300 days. Analysis of one of two transplantable tumor lines indicated that this transplant was of T- cell origin and thus atypical, since LL is thought to be a B-cell-dependent neoplasm. An etiologic role for RAV-O was not proved. (3 refs)

78-3946 **Suppression of the Mitogen-stimulated Blastogenic Response During Reticuloendotheliosis Virus-induced Tumorigenesis: Investigations into the Mechanism of Action of the Suppressor.** (Eng) Carpenter, C. R. (Dept. Microbiology, Univ. Texas at Austin, Austin, TX, 78712); Rubin, A. S.; Bose, H. R. *J Immunol* 120(4): 1313-1320; 1978.

The in vitro and in vivo kinetics of reticuloendotheliosis virus (REV)-induced suppression of the phytohemagglutinin (PHA) response of splenic lymphocytes were investigated. Using PHA-induced ^{3}H-thymidine uptake as an indication of the ability of spleen cells from REV-infected chickens to undergo blastogenesis, severe suppression of the response was demonstrated within 72 hr of REV infection. This suppression required active viral infection, since ip or iv injection of UV-inactivated REV did not result in inhibition of the blastogenic response. Suppressor cells from the spleens of REV-infected birds severely inhibited the ability of spleen cells from uninfected chickens to respond to PHA at a ratio of 1:20, suggesting that each suppressor cell may be capable of suppressing more than one target cell. Contact between suppressor and target cells was required for the rapid inhibition of the normal PHA response. The suppressive mechanism is cytostatic and apparently of host origin, since neither REV nor REV-infected (or transformed) cells mediated the suppression. The ability of the suppressor cells to impair the blastogenic response of spleen cells was sensitive to trypsin, suggesting that an inhibitory protein is exposed on the surface of the suppressor cells. In view of previous indications that early cytostatic suppressive events might inhibit cytotoxic immune reactions, the early appearance of this suppressor activity should favor tumorigenesis. (35 refs)

78-3947 **Morphological and Biochemical Differentiation in RSV Transformed Chick Embryo Myoblasts.** (Eng) Fiszman, M. Y. (Dept. Biologie Moleculaire, Institut Pasteur, 75015 Paris, France). *Cell Differ* 7(1/2): 89-101; 1978.

Morphological and biochemical differentiation was studied in chick embryo myoblasts transformed by a temperature-sensitive mutant of Rous sarcoma virus (RSV ts88). At the permissive temperature (36 C), the transformed myoblasts lost their ability to form myotubes and to express the biochemical markers of myogenic differentiation. No acetylcholine receptors were detected, few myosin heavy chains and no myosin light chains were synthesized, and only the B form of creatine phosphokinase was present in the cells. After a shift to the nonpermissive temperature (41 C), the normal differentiation process was restored; myotubes were formed that expressed muscle-specific proteins. Two mechanisms by which viral transformation may prevent myogenic differentiation are summarized. (20 refs)

78-3948 **Avian Retrovirus RNA-directed DNA Synthesis: Transcription at the 5′ Terminus of the Viral Genome and the Functional Role for the Viral Terminal Redundancy.** (Eng) Collett, M. S. (Dept. Pathology, Univ. Colorado Medical Sch., Denver, CO, 80262); Faras, A. J. *Virology* 86(2): 297-311; 1978.

The size and structure of the DNA synthesized in vitro on 35S RNA-transfer RNA-trp (tRNA-trp) template-primer complexes in reconstructed reactions by avian retrovirus RNA-directed DNA polymerase were elucidated. Under standard enzymatic reaction conditions, three major DNA species were initiated on tRNA-trp at the 5′ end of the viral genome. Two of these were single-stranded transcripts 70 and 100 nucleotides in length. The third was hairpin in structure and 185 nucleotides in length. A precursor-product relationship was being demonstrated between DNA_{70}, DNA_{100}, and the hairpin DNA_{185} species. Furthermore, the hairpin DNA_{185} appeared to form during DNA synthesis, rather than after DNA synthesis, as a consequence of the intramolecular folding of complementary sequences present in the DNA_{185} transcript. In addition to conversion of DNA_{100} to hairpin DNA, the DNA_{100} species could attach to the 3′ end of the viral genome, presumably by base pairing with the terminally redundant sequences at the 3′ terminus, to provide a primer for the continuation of DNA transcription at this end of the viral RNA. These data provide a functional role in proviral DNA synthesis for the terminally repeated genomic sequences. (46 refs)

78-3949 **Persistence, Induction and Transfection of Virus Genome in RSV-transformed Mammalian Cells.** (Eng) Svoboda, J. (Inst. Molecular Genetics, Czechoslovak Acad. Sciences, Prague, Czechoslovakia). *In: Characterization and Treatment of Human Tumours. Proceedings of the Seventh International Symposium on the Biological Characterization of Human Tumours held in Budapest, April 13-15, 1977.* Davis, W.; Harrap, K. R., eds. (Amsterdam: Excerpta Medica): Advances in Tumour Prevention, Detection and Characterization. Vol. 4, 332 pp.; 30-37; 1978.

The role of the avian sarcoma virus (ASV) *gag* gene in viral transfection was studied using Brown Leghorn chicken fibroblasts transfected by DNA isolated from duck cells that had been transformed by the ASV mutant LA 334. Following transfection, four viral isolates were obtained that were temperature-sensitive (ts) to transformation. The tests of ts lesion formation at the level of virus synthesis using chicken fibroblasts gave equivocal results. However, when the viral isolates were tested on duck cells, virus production was markedly increased at the nonpermissive temperature (41 C). These and other results suggest that the region of the virus genome responsible for coding for the *gag* gene products is specifically transferred during transfection. The importance of these findings to the molecular characteristics of provirus expression is outlined. (38 refs)

78-3950 **Preliminary Identification of the Number of *Sarc* Gene Protein Products of Rous Sarcoma Virus.** (Eng) Kamine, J. (Dept. Biology, Massachusetts Inst. Technology, Cambridge, MA); Burr, J. G.; Buchanan, J. M. *Adv Enzyme Regul* 16: 379-390; 1978.

The protein products made from virion RNA of transformation-defective (*td*) and nondefective (*nd*) Rous sarcoma virus (RSV) in a cell-free translation system were compared. Previously, two proteins of 25,000 and 18,000 daltons had been isolated by sodium dodecyl sulfate-polyacrylamide gelelectrophoresis from *nd* RSV but not from *td* RSV, which lacks the *sarc* gene. In these experiments, separation of RSV virion RNA on sucrose gradients showed that these two putative *sarc* gene products are synthesized as doublets from a messenger RNA (mRNA) of approx 18S. In addition to these two proteins, the 18S viral mRNA from *nd* RSV also directed the synthesis of a 60,000-dalton protein; this protein was absent or produced in much smaller amounts from the RNA of *td* RSV, suggesting that it may also be a *sarc*-specific protein. Three additional sizes of viral mRNA were found in *nd* and *ts* virions: the 38S genomic RNA that yields the 80,000-dalton *gag* gene precursor, a 28S RNA that yields a 55,000-dalton protein, and an RNA slightly smaller than 18S that yields a 37,000-dalton protein. Two-dimensional electrophoresis allowed the resolution of both bands of the 25,000 dalton doublet into several differently charged species. (34 refs)

78-3951 **Glycopeptides Derived from Individual Membrane Glycoproteins from Control and Rous Sarcoma Virus-transformed Hamster Fibroblasts.** (Eng) Tuszynski, G. P. (Wistar Inst. Anatomy and Biology, Philadelphia, PA, 19104); Baker, S. R.; Fuhrer, J. P.; Buck, C. A.; Warren, L. *J Biol Chem* 253(17): 6092-6099; 1978.

Membrane glycoproteins (gp's) from control (BHK_{21}/C_{13}) and Rous sarcoma virus-transformed (C_{13}/B_4) baby hamster kidney cells grown in medium containing (^{14}C- or D-3H-glucosamine were separated into two distinct classes by lithium diiodosalicylate (LiISal)-phenol extraction: a phenol-soluble fraction and an aqueous fraction. The phenol- and aqueous-soluble gp's differed in their sodium dodecyl sulfate-polyacrylamide gel profiles, polyacrylamide isoelectric focusing profiles, and glycopeptide distribution of Sephadex G-50. A number of aqueous- and phenol-soluble gp's from BHK_{21}/C_{13} and C_{13}/B_4 cells were purified to near homogeneity by polyacrylamide gel electrophoresis and gel electrofocusing. These gp's ranged in mol wt from 179,000 to 31,000 and had isoelectric points of 7.5-3.0. A comparison of 24 gp's from control and transformed cells showed that the pronase glycopeptides of 20 gp's from transformed cells gave rise to different Sephadex G-50 profiles than those from the homologous gp's from control cells. The exact chemical nature of these differences is not known, but they probably result from differences in sugar composition and/or oligosaccharide structure, which determine the size and shape of the glycopeptide. Such extensive alterations of membrane components could be the basis for the changes in cell behavior and growth properties that are known to accompany malignant transformation. (27 refs)

78-3952 **Immunogenicity of the Envelope Glycoprotein of Avian Sarcoma Virus.** (Eng) Halpern, M. S. (Wistar Inst. Anatomy and Biology, 36th St. at Spruce, Philadelphia, PA, 19104); Friis, R. R. *Proc Natl Acad Sci USA* 75(4): 1962-1966; 1978.

The humoral response to the type- and group-specific determinants of viral envelope glycoprotein (VGP) was measured after sensitization of chick helper factor-positive [chf(+)] and chf(-) chickens to the VGP of exogenous avian sarcoma virus (ASV). The expression of type E-specific glycoprotein (gpE) in chf(+) but not chf(-) chickens is not restricted to a certain stage of embryogenesis, but persists in postembryonic chickens during the development and maintenance of immunocompetence. Sensitization of chf(+) and chf(-) chickens resulted in the induction of detectable antibody reactivity to determinants of the VGP that were type-specific as well as group-specific. Because group-specific determinants were present on gpE, these results link immunity to exogenous (VGP) in chf(+) chickens with autoreactivity. It is hypothesized that the VGP is a thymus-dependent antigen and that helper T cells in chf(+) chickens are functionally unreactive to the group-specific determinants of the VGP because the endogenous gpE in chf(+) chickens renders specific T cells, (but not B cells) unresponsive. With chf(+) chickens, triggering of B cells reactive to group-specific determinants would occur by a carrier effect in which T cells are primed to foreign determinants associated with exogenous VGP, such as the type-specific determinants. The available amount of T cell help may determine the strength of the response to group-specific determinants. (12 refs)

78-3953 **Tumor-specific and Tumor-associated Membrane Antigens of Rous Sarcoma Virus Transformed Hamster Fibroblasts.** (Eng) Comoglio, P. M. (Dept. Human Anatomy, Sch. Medicine, Univ. Turin, Turin, Italy); Bertini, M.; Prat, M. *Int J Cancer* 22(1): 55-62; 1978.

The antigenic composition of hamster fibroblasts transformed in vitro by Rous sarcoma virus (RSV) mutants either defective for the synthesis of gp85 (*env-*) or temperature-sensitive for the ability to transform the host cell (*ts*) is reported. Xenogeneic antisera obtained by immunizing rabbits with the RSV-transformed fibroblasts recognized, in the ^{51}Cr-release cytotoxicity assay, at least two tumor-membrane antigens: (1) an antigen also common to hamster cells transformed by unrelated DNA and RNA oncogenic viruses (polyoma virus, mouse sarcoma virus, simian virus 40); and (2) a virus-induced cell-surface antigen (VCSA) that is virus-specific and is also expressed by rat, quail, and chicken cells transformed by RSV. By comparing the anti-VCSA serum with antisera directed against purified gp85, group-specific proteins, reverse transcriptase, or detergent-lysed virus particles, it was shown that VCSA is not a known virion structural protein. VCSA expression did not correlate with viral replication, since it was not detected in chick embryo fibroblasts productively infected with the transformation-defective Rous-associated virus 1, which shares virus structural genes with RSV. However, in hamster cells transformed by the RSV *ts* mutant, VCSA expression at the cell surface correlated with the expression of the transforming gene. It is concluded that VCSA is under the control of the *sarc* gene and that in this respect, it seems to be the mammalian counterpart of the avian tumor-specific surface antigen. (38 refs)

78-3954 **Virus-like Particles Associated with the Mitochondria of Ethidium Bromide Treated Transformed Cells.** (Eng) Soslau, G. (Dept. Biological Chemistry, Hahnemann Medical Coll. and Hosp., Philadelphia, PA, 19102). *J Gen Virol* 40(part 1): 245-251; 1978.

Electron microscopy and enzyme studies demonstrated the production of mitochondria (M)-associated viruslike particles in baby hamster kidney cells transformed by the Bryan strain of Rous sarcoma virus (RSV) when they were treated with ethidium bromide (EB). These cells, line C_{13}/B_4, are normally nonproducers. However, when C_{13}/B_4 cells were grown in the presence of 2 μg/ml EB for 4 days, electron microscopy showed that their matrix was less dense than that of untreated cells and that viruslike particles were associated with the M. These particles were never observed in the M of untreated cells. M-associated virus particles have also been observed in an EB-resistant cell line ($B_4EB\text{-}R_2$, developed from C_{13}/B_4 cells) that has been cultured and cloned in the presence of 2 μg/ml EB for > 2 yr. The number of viruslike particles was enhanced when the $B_4EB\text{-}R_2$ cells were treated with 8 μg/ml EB for 4 days. Enzyme studies assaying for an RNA-dependent DNA polymerase [reverse transcriptase (RT)]-type activity were performed to support the electron microscope findings. Both C_{13}/B_4 and $B_4EB\text{-}R_2$ cells were positive for the presence of an RT-like enzyme associated with the M. The enzyme activity was not related to a terminal transferase, it had the characteristics of the virus RT with respect to template preference, and it was found at the buoyant density of the presumptive virus before and after treatment with Triton X-100. These results confirmed that a virus-like particle is induced by EB in both cell lines. It is not clear whether the particles are derived from integrated RSV information or they represent an endogenous species. (31 refs)

78-3955 **Simultaneous Production of Mouse Endogenous Virus and Rous Sarcoma Virus by Schmidt-Ruppin Virus Infected Mouse Cells.** (Eng) Kotler, M. (Lab. Molecular Virology, Hebrew Univ.-Hadassah Medical Sch., Jerusalem, Israel); Lerer, I.; Ben Moyal, Z.; Spira, G. *J Gen Virol* 40(part 1): 141-150; 1978.

This study shows that injection of Schmidt-Ruppin Rous sarcoma virus subgroup D (SRV-D)-infected chick cells into C3H/f newborn mice gives rise to mouse tumor cells capable of expressing antigens of both avian sarcoma and mouse leukemia viruses and of producing C-type particles. Sc injections of 1 x 10^6 chick embryo fibroblasts transformed by SRV-D into the mice gave rise to tumors at the injection site after approx 60 days in about 40% of the mice. These tumors were transplantable in C3H/f mice and, after 18 passages, were able to induce tumors in the wing web of adult Leghorn chickens. Tumor cells from the 18th passage were also used to establish a cell line (C3HSR) in tissue culture. These cells released C-type virus particles that produced foci and were able to propagate in chick cells. The C3HSR cells were tested in complement fixation studies performed with antisera against Moloney murine leukemia virus (MuLV) p30 antigen, feline leukemia virus, and SRV-D. C3HSR cell extracts gave positive results with all three antisera, indicating that these cells express both avian and mammalian virus antigens. Examination of three subclones of C3HSR cells by immunofluorescence showed that both avian and mammalian antigens are produced by the same cell. Mouse cells infected with virus released by C3HSR cells produced MuLV-like particles, as revealed by the reverse XC syncytial test and by immunofluorescence tests. (24 refs)

78-3956 **Brain Tumors Induced in Hamsters by Intracerebral Inoculation of SR-RSV-Infected Embryonic Brain Cells.** (Eng) Nakazato, Y. (First Dept. Pathology, Gunma Univ. Sch. Medicine, 3-39-22 Showa-machi, 371 Maebashi-shi, Gunma-ken, Japan); Ishida, Y. *Acta Pathol Jpn* 28(3): 445-457; 1978.

Brain tumors were induced in Syrian hamsters by the intracerebral inoculation of brain cells obtained from 12-day-old syngeneic hamsters and infected in vitro with the Schmidt-Ruppin strain of Rous sarcoma virus (SR-RSV). A total of 212 tumors developed in all 25 recipients 19-125 days after transplantation. On the basis of light and electron microscopy, they were classified into four main groups: astrocytoma (45.8%), pleomorphic glioma (50.0%), sarcoma (3.8%), and unclassified (0.4%). The morphological features of these tumors are described, and the advantages of this brain tumor model are discussed. (22 refs)

78-3957 **Polyethylene Glycol-mediated Infection with Avian Sarcoma Viruses. Brief Report.** (Eng) Rohde, W. (Institut fur Virologie, Fachbereich Humanmedizin, Justus Liebig-Universitat Giessen, Frankfurter Strasse 107, D-6300 Giessen, W. Germany); Pauli, G.; Henning, J.; Friis, R. R. *Arch Virol* 58(1): 55-59; 1978.

The use of polyethylene glycol-induced fusion of viral and cellular membranes to overcome genetically determined resistance to infection is reported. Using this method, avian sarcoma virus-transformed mammalian cells were produced; these cells will be useful for the study of Rous sarcoma virus-specific tumor antigens. (11 refs)

78-3958 **Different Types of Virus-specific RNA in Mammalian Cells Transformed by Rous Sarcoma Virus as Revealed by Molecular Hybridization Tests.** (Eng) Kisseljov, F. L. (Cancer Res. Center, Moscow, USSR); Tatosyan, A. G.; Svoboda, J. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 271-273; 1978.

Rous sarcoma virus-specific RNA was analyzed in virogenic XC rat cells and nonvirogenic RVP-3 and RVA-4 mouse cells. No virus-specific RNA was found in the cytoplasm of RVA-4 cells. RVP-3 and XC cells differed from each other with respect to the presence of viral group-specific antigen. These cells contained virus-specific RNA's that were transcribed from different parts of the integrated viral genome. (26 refs)

78-3959 **Restriction Enzyme Sites on the Avian RNA Tumor Virus Genome.** (Eng) Taylor, J. M. (Inst. Cancer Res., Fox Chase Cancer Center, Philadelphia, PA, 19111); Hsu, T. W.; Lai, M. M. *J Virol* 26(2): 479-484; 1978.

Full-size single-stranded DNA transcripts of the avian RNA tumor virus genome were isolated from the products of the endogenous reaction of detergent-disrupted avian sarcoma virus (ASV) particles. These transcripts were converted with *Escherichia coli* DNA polymerase I and ^{32}P-labeled nucleoside triphosphate precursors, in the presence of oligodeoxyribonucleotide primers, into labeled double-stranded DNA. The latter DNA was used to map the sites of action of seven restriction enzymes (*Pvu* I, *Hpa* I, *Kpn* I, *Xba* I, *Eco*RI, *Hin* dIII, and *Xho*I) on ghe genome of three strains of ASV (Prague B, Prague C, and Bratislava 77). The site on the genome where transcription of complementary DNA ultimately stops has not been determined; there may be different results for in vitro and in vivo transcription. The immediate application of the restriction data obtained from this study is to characterize those ASV DNA species, both integrated and unintegrated, that can be detected in infected avian cells. (19 refs)

78-3960 **Kinetics of Synthesis, Structure and Purification of Avian Sarcoma Virus-specific DNA Made in the Cytoplasm of Acutely Infected Cells.** (Eng) Varmus, H. E. (Dept. Microbiology, Univ. California, San Francisco, CA, 94143); Heasley, S.; Kung, H. J.; Oppermann, H.; Smith, V. C.; Bishop, J. M.; Shank, P. R. *J Mol Biol* 120(1): 55-82; 1978.

A virus-specific DNA synthesized in the cytoplasm of quail tumor cells acutely infected with the Bratislava-77 strain of avian sarcoma virus was characterized by rate-zonal sedimentation and polyacrylamide gel electrophoresis in conjunction with molecular hybridization reagents specific for various regions of the viral genome. The rate of appearance and elongation of the viral strands was sufficiently slow and synchronous to permit a description of the order of principal events in the synthesis of the cytoplasmic linear duplex. The description is completely compatible with the events described for reactions in vitro. Moreover, a homogeneous species of short strands (approx 250-300 nucleotides) with the same polarity as the viral genome was identified that contains sequences derived from both the 3′ and 5′ termini of the viral genome. In addition, the (-) strand of viral DNA, which is complementary to the viral genome, was purified from the cytoplasm of infected cells, and radiolabeled (+) strands were synthesized in vitro with *Escherichia coli* DNA polymerase I, using extremely small quantities (approx 10 nanograms) of purified (-) strands as template. 78-3961 **Transmission of B77 Virus Double Mutant LA334 Markers by Transfection.** (Eng) Stetina, R. (Inst. Experimental Medicine, Czechoslovak Acad. Sciences, 515 83 Olesnice v Orlickych horach, Praha 6, Czechoslovakia); Mach, O.; Svoboda, J. *Intervirology* 10(5): 276-288; 1978.

The successful transfection of chicken fibroblasts with DNA isolated from LA334-transformed duck cells and determination of temperature-sensitive (*ts*) lesions in the *src* and *gag* genes in the progeny viruses are reported. LA334 is the double mutant of avian sarcoma virus B77: it has two independent *ts* lesions, in virus transformation and replication, that implicate mutations in the respective *src* and *gag* genes. The exposure of chick fibroblasts from Brown Leghorn embryos to 1.5 and 3.0 μg DNA/culture transfected 1/6 and 3/9 cultures, respectively. Thus, lowering the DNA concentration decreased the efficiency of transfection. Similar attempts to transfect duck embryo fibroblasts were not successful. The four viruses recovered after transfection were all ts for transformation. Two were fully ts for replication, as shown by analysis of virus replication, by characterization of virus particles produced at the nonpermissive temperature (41 C) using density gradient centrifugation, and by electron microscopy. The other two viruses were only partially ts for replication. It is suggested that both the *src* and *gag* regions of the avian sarcoma virus genome are transferred simultaneously during transfection, probably by a single integral provirus copy. (37 refs)

78-3962 **Inactivation of Turkey Herpesvirus by UV Light.** (Eng) D'Aprile, P. (Instituto Zooprofilattico Sperimentale delle Venezie, Via G. Orus, 2, 35100 Padua, Italy); Petek, M. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 247-248; 1978.

The UV inactivation rate of turkey herpesvirus (HVT) was compared with that of Pseudorabies virus (PSRV). The UV inactivation curves of HVT were one-component but those of PSRV were two-component, and the former was more resistant to UV light than the latter. The high resistance of HVT was partially due to host cell reactivation. Caffeine treatment of host cells reduced this reactivation. A multiple reactivation effect was noted for PSRV but not for HVT. (2 refs)

78-3963 **Characterization of a Nonproductive Cell Line, MKT-1, Established from a Marek's Disease Tumor of Kidney in a Chicken.** (Eng) Nonoyama, M. (Lab. Molecular Virology, Life Sciences, Inc., St. Petersburg, FL, 33710); Tanaka, A.; Silver, S.; Mitchen, J. R.; Smith, M.; Plasencia, R. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 193-194; 1978.

The status of Marek's disease virus (MDV) genomes in MKT chicken lymphoblast cells was determined. Most MDV DNA existed as nonintegrated plasmid DNA with the characteristics of a closed, circular molecule. Since similar observations were made in herpesvirus saimiri-transformed cells, this form of DNA must be common in the genomes of tumor-inducing herpesviruses. Transcription studies in MKT cells indicated that approx 20% of the viral genome is transcribed. A similar amount of Epstein-Barr virus DNA is transcribed in Raji cells. (6 refs)

78-3964 **Relationship of Intracisternal A-Particles from Mouse Myelomas to C-Type Virus.** (Eng) Weimann, B. J. (Basel Inst. Immunology, CH-4005 Basel 5, Switzerland); Schmidt, J.; Pragnell, I. B.; Takacs, B. J. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.;

Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 240-241; 1978.

Intracisternal A particles were isolated from mouse myeloma cells, and the DNA polymerase that eluted at 0.30 M KCl was compared with that of the C-type Abelson murine leukemia virus (A-MuLV). Both enzymes had a mol wt of 80,000 daltons, had almost identical slopes of inhibition, responded to the same polynucleotides, and carried ribonuclease H. Purified RNA from the A particles formed stable hybrids with a DNA probe synthesized in vitro from A-MuLV. (2 refs)

78-3965 **The Use of Nucleic Acid Hybridization to Demonstrate Relatedness Between the Naturally Occurring and Laboratory Strains of Murine C-type Viruses.** (Eng) Chattopadhyay, S. K. (Pediatric Oncology Branch, NCI, Bethesda, MD, 20014); Lander, M. R.; Kramer, B. S.; Hartley, J. W.; Levine, A. S.; Rowe, W. P. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIth International Symposium on Comparative Research on Leukemia and Related Disease, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 448-451; 1978.

^{3}H-DNA probes were used in hybridization reactions to confirm the finding that naturally occurring murine leukemia viruses (MuLV) are either ecotropic, xenotropic, or amphotropic. The entire genomes of the xenotropic viruses NZB-IU-1 and BALB-IU-1 and the amphotropic strain 1504 were present in the DNA of all inbred strains studied. Each of these three classes is biochemically distinct; ie, 20% of their genomes are comprised of host-derived sequences. Half the unique sequences of certain naturally occurring MuLV may be present in the genomes of laboratory viral strains. (13 refs)

78-3966 **The Early Appearance and Subsequent Distribution of Murine Leukaemia Virus in NZB Embryos.** (Eng) East, J. (Imperial Cancer Res. Fund, Mill Hill, London, England); Tilly, R. J.; Tuffrey, M.; Harvey, J. J. *Int J Cancer* 22(4): 495-502; 1978.

The location and distribution of murine leukemia virus (MuLV) particles were examined by electron microscopy in New Zealand Black (NZB) mouse embryos from before implantation (at 4.5 days after mating) until the 14th day of embryonic life. AKR, BALB/c, and (BALB/c x NZB)F_1 eggs were included for comparison of preimplantation phases, and five combinations of blastocysts fused in vitro as six- to eight-cell eggs were also examined. Four variants of A-type particles were distinguished, and they were associated with cisternae of the endoplasmic reticulum. All four replicated at some stage of preimplantation development in NZB and AKR eggs as well as in fused AKR <--> AKR and BALB/c <--> BALB/c blastocysts, and three were found in 8- or 14-day NZB embryos. The smallest A-type variant also appeared in one-cell unfertilitized NZB eggs, indicating that its production did not depend on fertilization. Immature C-type virus was first seen in 5-day NZB implants. The spleen of 12-day NZB embryos was the first discrete organ in which virus could be visualized, and it contained both immature C-type particles and one of the A-type variants. No mature C-type virus was detected. Coincidentally, huge numbers of immature and mature C-type MuLV were found distending the uterine glands of pregnant NZB females carrying 5- or 7-day implants. This unrestrained virus replication was not related to implantation, because the same pattern was seen in the uterine glands of 7/8 age-matched virgin NZB females. The lack of infectivity of A-type particles coupled with their genetic transmission and their ubiquity in NZB embryos may indicate that they are xenotropic. (32 refs)

78-3967 **Genetic Relationship of Wild Mouse Amphotropic Virus to Murine Ecotropic and Xenotropic Viruses.** (Eng) Bryant, M. L. (Dept. Pathology, Univ. Southern California Sch. Medicine, Los Angeles, CA, 90033); Roy-Burman, P.; Gardner, M. B.; Pal, B. K. *Virology* 88(2): 389-393; 1978.

The general nucleic acid homology between amphotropic and ecotropic wild mouse (*Mus musculus*) leukemia viruses (MuLV) and between these viruses and the ecotropic and xenotropic MuLV's of inbred mice was determined. The degree of homology was ascertained by DNA-RNA hybridization using viral complementary DNA and polyadenosine-containing 70S viral RNA. The results indicated that the genomes of individual cloned amphotropic and ecotropic wild mouse virus isolates were closely related. Furthermore, these nucleotide sequences were closely related to, but distinguishable from, the genomes of prototype ecotropic (Rauscher, Gross-AKR) and xenotropic (AT-124, NZB, AKR, BALB/c) MuLV's of inbred mice. (24 refs)

78-3968 **Murine Leukemia Virus in Chemically-induced Sarcomas as Detected by XC Plaque Formation.** (Eng) Basombrio, M. A. (Academia Nacional de Medicina, Las Heras 3092, 1425 Buenos Aires, Argentina); Pasqualini, C. D. *Arch Geschwulstforsch* 48(4): 308-312; 1978.

Endogenous murine leukemia virus (MuLV) was detected in short-term in vitro cultures of primary autochthonous sarcomas induced by sc implantation of 320 μg of 3-methylcholanthrene (3-MC) in CBF_1 mice. In direct XC syncytium assays, 13/31 cultures induced >4 syncytium plaques per flask. In seven tumors, the plaques numbered >200 or were confluent. The titers found in individual tumors were definitely higher than those that could be expected solely from endogenous, naturally occurring oncornaviruses present in animals of the same age and sex. All 39 normal spleen cultures had <4 plaques; 31 cultures had no plaques at all. It is postulated that the increased titer of virus was a result rather than a cause of tumor induction by chemicals. The association of MuLV with 3-MC-induced tumors may be due to in vitro conditions, which may favor endogenous MuLV replication in sarcoma cells. (14 refs)

78-3969 **Efforts to Control Type C Virus Expression in Wild Mice.** (Eng) Gardner, M. B. (Dept. Pathology, Univ. Southern California Sch. Medicine, Los Angeles, CA, 90033); Klement, V.; Henderson, B. E.; Estes, J. D.; Dougherty, M.; Casagrande, J.; Huebner, R. J. *Prog Cancer Res Ther* 2: 391-407; 1977.

The possibility of genetic control of the indigenous murine leukemia virus (MuLV) in Lc wild mice was studied. LC mice were crossbred with the inbred laboratory mouse strain B10. In contrast to the LC parents, there was an almost complete absence of detectable spleen CF group-specific (gs) antigen in the reciprocal B10 x LC F_1 hybrids and in the reciprocal F_1 and F_2 B10 backcrosses. It was more prevalent in the F_2 generation and in the F_1 backcross to LC mice. Suppression of gs antigen expression was correlated with a suppression of infectious MuLV production, and in the F_1 hybrids, lymphoma was significantly reduced in incidence and delayed in onset, and paralysis was essentially eliminated. Of the five lymphomas in F_1 hybrids, only two appeared similar to the LC lymphomas in their pathologic and virologic features. A breast carcinoma, a lung adenoma, and an adrenal adenoma also occurred in three respective F_1 hybrids with LC mothers. Attempts to actively immunize LC mice after the neonatal period with their indigenous MuLV and to prevent lymphoma and paralysis were not successful, apparently because of relative tolerance to this virus. The Fv-1 allele from the B10 mice and an additional gene(s) appeared to be responsible for the genetic control of MuLV expression and the related diseases in the B10 x LC hybrids. (35 refs)

78-3970 **Relationship of Endogenous Murine Xenotropic Type C Virus Production to Spontaneous Transformation of Cultured Cells.** (Eng) Avery, R. J. (Dept. Biological Sciences, Univ. Warwick, Coventry CV4 7AL, England); Levy, J. A. *J Gen Virol* 39(3): 427-435; 1978.

An investigation was made of (1) the regulation of spontaneous production of endogenous xenotropic viruses by clones of New Zealand Black (NZB) mouse embryo cells and (2) the interaction between endogenous virus production and the ability of clones to transform spontaneously. All clones derived from the established NZB-Q cell line produced xenotropic virus but at different titers; the level of production varied between 10^2 and 10^4 infectious particles/ml. Virus production was constant over several passages. A series of subclones derived from each clone produced titers of virus identical to that of the parental clone. These data indicate that the NZB-Q line was composed of cells with varying degrees of virus expression that could be separated by cloning. Foci of cell alteration occurred spontaneously in some of the clonal lines after 6 to 10 passages. The amount of virus generated did not correlate with the spontaneous transformation of NZB, NIH Swiss, or BALB/c mouse cells. It is concluded that individual mouse cells differ in their intracellular regulation of xenotropic virus expression but that this control, once established, remains constant. The findings also indicate that spontaneous cellular transformation does not alter the intracellular control of virus production. (21 refs)

78-3971 **Oncogenicity of Friend-Virus-infected Cells: Determination of Origin of Spleen Colonies by the H-2 Antigens as Genetic Markers.** (Eng) Wendling, F. (Unite de Physiologie Cellulaire de l'INSERM--U. 22, Fondation Curie-Institut du Radium, Faculte des Sciences, Batiment 110, 91405 Orsay, France); Tambourin, P. E. *Int J Cancer* 22(4): 479-486; 1978.

The origin of spleen colonies in semiresistant hybrid mice inoculated with Friend leukemia virus (FLV)-infected cells was determined with the use of histocompatibility (H-2) antigens as genetic markers. The standard cytotoxicity test was used to characterize the H-2 antigens present on the surface of spleen cells from normal or FLV-infected leukemic parents or F_1 hybrid mice. Colonies obtained from the spleens of (C3H x C57BL/6)F_1 recipients (H-2k/H-2b) 10 days after iv graft of FLV-infected spleen cells of C3H origin (H-2k) were sensitive to anti-C57BL/6 antibodies. Colonies obtained from the spleens of (DBA/2 x C57BL/10)F_1 recipients (H-2d/H-2b) grafted with DBA/2 leukemic spleen cells (H-2d) were sensitive to both anti-H-2b and anti-H-2d antibodies. These results prove that the main cell population constituting a spleen colony originates from the recipient. It is concluded that spleen colonies do not result from the neoplastic proliferation of injected donor cells but rather from the multiplication of host cells transformed by Friend virus produced by the grafted cells. (37 refs)

78-3972 **Origin of Spleen Colonies Generated by Friend Virus-infected Cells in Mice.** (Eng) Steeves, R. A. (Dept. Genetics, Albert Einstein Coll. Medicine, Yeshiva Univ., 1300 Morris Park Ave., Bronx, NY, 10461); Bubbers, J. E.; Plata, F.; Lilly, F. *Cancer Res* 38(9): 2729-2733; 1978.

"Tumor colonies" develop in the spleen of unirradiated C57BL/6 x DBA/2 F_1 (BD2F_1) mice (*H-2b/H-2d*) 9 days after iv injection of spleen cells from N-tropic Friend virus(FV)-infected DBA/2 donors (*H-2d/H-2d*). To determine whether these spleen colonies resulted from donor or host cell proliferation, the histocompatibility antigen markers of cell populations from dissected colonies and intercolonial areas were compared. Cytotoxic tests with mouse antisera specific for *H-2Db* and *H-2Dd* antigens revealed the presence of both antigen specificities on cells from both sources, indicating that most cells were of host BD2F_1 origin. The presence of donor cells in spleen colonies could be detected, however, when the recipients were lethally irradiated (800 R) BD2F_1 mice, the colonies of which consisted exclusively of cells bearing *H-2Dd* and not *H-2Db* (recipient) antigens. Analogous results were obtained by cytotoxic analysis of spleen colonies in C57BL/6 x C3H/An F_1 mice injected with FV-infected C3H/An spleen cells. In addition, direct visualization of virus-induced antigens and *H-2* antigens by immunofluorescent staining confirmed the cytotoxicity data. The colony-forming efficiency of *H-2d* cells was found to vary only slightly among unirradiated recipients of different *H-2* haplotypes. These findings indicate that spleen colony formation by FV-infected leukemia cells was based on donor cell proliferation in irradiated hosts and on host cell proliferation in unirradiated hosts (for the strains used here). The spleen colony assay for Friend leukemia cells in unirradiated hosts is therefore an assay for infectious centers in which virus is apparently released from donor cells in quantities sufficient to infect *Fv-1*-restrictive host cells and to initiate their proliferation. (21 refs)

78-3973 **In Vitro Infection of Mouse Hemopoietic Cells by Friend Virus as Measured by a Spleen Colony Assay for Infectious Centers.** (Eng) Steinheider, G. (Dept. Genetics, Albert Einstein Coll. Medicine, Bronx, NY); Bubbers, J. E.; Steeves, R. A. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 291-294; 1978.

Spleen colony formation was studied in unirradiated or irradiated (850 rads) BDF_1 mice inoculated iv with leukemic spleen cells (5 x 10^4 cells per animal) from Friend virus (FV)-infected DBA/2 mice. Nine days later, the histocompatibility antigen (H-2) type of the colony cells was compared with that of donor and recipient mice. The results showed that spleen colony formation by FV leukemia cells was based on donor cell proliferation in irradiated hosts and on host cell proliferation in unirradiated hosts. Thus, the injected cells acted as infectious centers (IC) in the unirradiated animals, releasing sufficient virus to Fv-1-restrictive host cells. IC were also generated after in vitro infection with FV. To study the effect of the Fv-2-resistant (r) gene on in vitro infection, infected bone marrow cells from DBA/a and congenic D2.Fv-2r mice were injected into CDF_1 and (BALB/c x D2.Fv-2r) hybrids, respectively. The frequency of IC was tenfold higher in DBA/2 cells than in D2.Fv-2r cells. The Fv-2-resistant animals may have fewer target cells for FV infection or their bone-marrow cells may release less virus after infection. (4 refs)

78-3974 **Studies on the Interaction Between Chemical Carcinogens and Leukemia Viruses for the Promotion of Cellular Transformation and Mutagenesis.** (Eng) Mishra, N. K. (Microbiological Associates, Bethesda, MD, 20014); Premkumar-Reddy, E.; Aulakh, G. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 249-250; 1978.

The relationship between chemical carcinogens and leukemia viruses for the promotion of cellular transformation was investigated. When Fischer rat embryo cells were infected with Rauscher leukemia virus and exposed to several carcinogens, transformation was accelerated and ouabain-resistant colonies were induced. Carcinogen treatment did not lead to an additional accumulation of viral genomes in the host DNA. The interactions between chemical carcinogens and leukemia viruses are concluded to be complex and probably multistep events. (no refs)

78-3975 **Immune Reactivity of RBL-3, a Nonproducer Leukemia Induced by Rauscher Murine Leukemia Virus in C57BL/6 Mice.** (Eng) Chang, K. S. (Viral Oncogenesis Section, Lab. Cell Biology, NCI, NIH, Public Health Service, U.S. Dept. Health, Education, and Welfare, Bethesda, MD, 20014). *J Natl Cancer Inst* 61(1): 107-112; 1978.

The in vitro characteristics of RBL-3, a Rauscher murine leukemia virus (R-MuLV)-induced leukemia of C57BL/6 mice, were investigated along with its virus inducibility by 5-iodo-2′-deoxyuridine (IUdR) and its oncogenicity and immune reactivity. No infectious virus particles were found, but viral structural proteins were detected on the membrane of RBL-3 cells by membrane immunofluorescence when cells were treated with anti-gp69/71 or anti-p30 serum. An NB tropic virus indistinguishable from R-MuLV was recovered after treatment with IUdR (optimal concentration, 200 μg/ml). Dexamethasone treatment slightly boosted the production of activated virus but did not by itself activate the virus. RBL-3 cells had Fc receptors, but no Thy 1.2 antigen or surface immunoglobulin. In mice inoculated with RBL-3 ip, the sc tumor mass and the spleens and lymph nodes showed some characteristics of a reticulum cell neoplasm, but their undifferentiated appearance did not permit definite classification. RBL-3 cells exhibited the Friend-Moloney-Rauscher virus-specific transplantation antigen, as shown by their immunosensitivity and immunogenicity in tumor rejection experiments. Crude membrane and crude soluble antigen preparations obtained from RBL-3 membranes retained the capacity to induce tumor rejection. These results indicate that RBL-3 leukemia is a virus nonproducer that contains an R-MuLV genome that can be activated. (24 refs)

78-3976 **Cellular Membrane Receptors for Oncovirus Envelope Glycoprotein: Properties of the Binding Reaction and Influence of Different Reagents on the Substrate and the Receptors.** (Eng) Bishayee, S. (Indian Inst. Experimental Medicine, 4, Raja Subodh Mullick Road, Calcutta 700032, India); Strand, M.; August, J. T. *Arch Biochem Biophys* 189(1): 161-171; 1978.

The binding of the purified envelope glycoprotein (gp69/71) of Rauscher murine C-type oncovirus (RaV) to intact cells and cell membranes was characterized. The binding of radiolabeled gp69/71 was specific to cells permissive to RaV infection (NIH 3T3, BALB/c 3T3, SC-1 and Swiss 3T3FI). There was no binding to mink, rabbit cornea, and human muscle/skin cells, which are nonpermissive to this virus. Specificity was also demonstrated with respect to viral interference: NIH 3T3 cells infected with Ra, Gross, or BALB/c N-tropic virus; BALB/c cells infected with endogenous BALB/c B-tropic virus; and SC-1 cells infected with Ra or AKR virus failed to bind gp69/71. In contrast, NIH cells infected with Moloney sarcoma virus, BALB/c cells infected by Kirsten sarcoma virus, and SC-1 cells infected with BALB xenotropic virus bound the virus envelope gp. The data suggest that recognition of host cells occurs immediately upon absorption and does not require penetration of the cell or modification of the envelope gp. The interaction is reversible, the gp dissociated from the cells by incubation with EDTA shows no change in size, and a substantial fraction of the dissociated gp is capable of repeated binding to cells. Studies of the effect of chemical modification on the ptor binding is a function of the protein moiety, not the carbohydrate one. Treatment with chemicals acting on protein confirmations resulted in substantial loss of activity. In contrast, digestion of gp69/71 with neuraminidase alone or with β-galactosidase did not affect binding activity. The marked sensitivity of gp68/71 membrane binding sites to trypsin, chymotrypsin, and phospholipase C indicates that the receptor is probably a protein and that it may require lipid for its activity or for the integrity of the membrane. (45 refs)

78-3977 **Biosynthesis of Reverse Transcriptase from Rauscher Murine Leukemia Virus by Synthesis and Cleavage of a *gag-pol* Read-through Viral Precursor Polyprotein.** (Eng) Kopchick, J. J. (Dept. Biology, Univ. Texas System Cancer Center, M.D. Anderson Hosp. and Tumor Inst., Houston, TX, 77030); Jamjoom, G. A.; Watson, K. F.; Arlinghaus, R. B. *Proc Natl Acad Sci USA* 75(4): 2016-2020; 1978.

The synthesis of reverse transcriptase (RT) from Rauscher murine leukemia virus (RLV) was studied in RLV-infected NIH Swiss mouse embryo fibroblasts (JLS-V16) and BALB/c spleen-thymus (JLS-V5) cell lines. RT was synthesized in the infected cells by way of a read-through polyprotein of 200,000 mol wt (Pr200-*gag-pol*), which was precipitated by antiserum to RT. PR200-*gag-pol* contains both p30 and RT peptide sequences. Intermediate RT-related precursors of 145,000 (Pr145-*pol*), 135,000 (Pr135-*pol*), and 125,000 (Pr125-*pol*) mol wt were specifically recognized by precipitation from infected cell extracts by antiserum to RT. These proteins shared methionine-containing tryptic peptide sequences with a virion polypeptide of 80,000 mol wt (p80-*pol*) precipitable by antiserum to RT. Purification of active RT enzyme from virions labeled with ^{3}H methionine showed that p80-*pol* was the major component. A polypeptide (Pr80-*pol*), similar in size to and having a nearly identical peptide map to that of mature viral p80-*pol*, was also precipitated from infected cells by antiserum to RT. Pulse-chase studies indicated that Pr80-*pol*, Pr125-*pol*, and Pr135-*pol* were stable polypeptides, but that Pr200-*gag-pol* and Pr145-*pol* were unstable precursors. Pulse-chase studies with cycloheximide showed that the processing of Pr200-*gag-pol* occurred for a short time (30 min) in the absence of protein synthesis. (15 refs)

78-3978 **Morphological Conversion of 'Immature' Rauscher Leukaemia Virus Cores to a 'Mature' Form after Addition of the P65-70 (*gag* Gene Product) Proteolytic Factor.** (Eng) Yoshinaka, Y. (Worcester Foundation of Experimental Biology, Inc., Shrewsbury, MA, 01545); Luftig, R. B. *J Gen Virol* 40(part 1): 151-160; 1978.

Studies showed that a partially purified proteolytic factor from Rauscher leukemia virus (RLV) specifically cleaves P65-70, the *gag* gene precursor polyprotein, to p30 and that this cleavage is accompanied by a change of the RLV core in the intact virion from an immature to a mature form. To analyze which substructures of the intact virion were necessary for this large-scale morphological conversion to occur, an attempt was made to duplicate the process in vitro. When the factor was added at increasing concentrations to immature core subparticles of RLV, there was an increasing amount of cleavage of both P65-70 and P40 (an intermediate cleavage product containing p30) to p30. Electron microscopy showed that this cleavage was correlated with the disappearance of immature cores and the appearance of mature cores. Apparently, the concentric coil of the immature core region opened up and was converted through a series of ill-defined stages into mature cores. The mature cores had a hexagonal profile, did not contain any outer micellar material, and were about 7 nanometers smaller than the immature forms. Intermediate structures that retained elements of both forms were also observed, suggesting that the in vitro conversion occurs on a 1:1 basis. The fact that the conversion could be duplicated in vitro eliminates the outer virion envelope and glycoprotein spikes as required functional elements for this process. (16 refs)

78-3979 **Binding of tRNA to Reverse Transcriptase of RNA Tumor Viruses.** (Eng) Panet, A. (Dept. Virology, Hebrew Univ., Hadassah Medical Sch., Jerusalem, Israel); Berliner, H. *J Virol* 26(2): 214-220; 1978.

The interaction of transfer RNA (tRNA) with the reverse transcriptase (RT) of Moloney murine leukemia virus (M-MuLV) and simian sarcoma virus (SiSV) was examined. The purified RT of the viruses sedimented in glycerol gradients as a globular protein with a mol wt of 70,000. After interaction with tRNA, however, the enzyme cosedimented with a protein of 150,000 molecular wt. The enzyme complexes were partly dissociated by degradation of the tRNA moiety by pancreatic RNase A. The RT released from virions of M-MuLV, SiSV, and avian myeloblastosis virus (AMV) by nonionic detergent migrated faster on glycerol gradients than the purified enzyme preparation. This was probably due to complex formation between part of the virion enzyme and the tRNA, which is endogenous in virions. However, addition of exogenous tRNA was needed to quantitatively complex all the virion RT of M-MuLV and SiSV. The RT of M-MuLV did not show tRNA species specificity in the binding reaction when glycerol gradients were used for assay. Several tRNA species of *Escherichia coli*, yeast, chicken, and rat origin were able to complex with the enzyme. AMV RT also bound tRNA species of *E. coli*, yeast, and chicken origin. These results demonstrate that the RT of mammalian RNA tumor viruses exists in two forms; the purified enzyme is a single polypeptide with a mol wt of 70,000 that is converted into a 150,000-mol wt complex after binding of tRNA. (25 refs)

78-3980 **Genomic Masking of Nondefective Recombinant Murine Leukemia Virus in Moloney Virus Stocks.** (Eng) Fischinger, P. J. (Lab. Viral Carcinogenesis, NCI, Bethesda, MD, 20014); Blevins, C. S.; Dunlop, N. M. *Science* 201(4354): 457-459; 1978.

HIX virus cloned from Moloney leukemia virus (M-MuLV) stock is a nondefective, leukemogenic, and amphotropic murine oncornavirus with a recombinant-type major glycoprotein (gp71). Newborn mice inoculated with HIX virus produced lymphomas that were indistinguishable from the original M-MuLV-induced disease. Although M-MuLV stocks generally contain little or no free amphotropic virus, dilution analysis of several virus stocks and the examination of virus progeny from individual foci revealed that HIX virus is present and functionally coated with ectropic Moloney virus envelopes. De novo generation of recombinant virus apparently is rare or does not occur in tissue culture. The presence of recombinant, nondefective, and leukemogenic HIX virus in M-MuLV stocks has a counterpart in MCF virus, which is related to AKR-MuLV. Because most mice have serum factors that inactivate recombinant viruses, genomic masking may be operative as a general survival mechanism for HIX and other analogous recombinant viruses. (16 refs)

78-3981 **Virus-specific RNA Synthesis in Interferon-treated Mouse Cells Productively Infected with Moloney Murine Leukemia Virus.** (Eng) Fan, H. (Tumor Virology Lab., Salk Inst., San Diego, CA, 92112); MacIsaac, P. *J Virol* 27(2): 449-452; 1978.

NIH-3T3 mouse cells productively infected with Moloney murine leukemia virus (M-MuLV clone 1 cells) were treated with interferon (IF: 30 units for 16-24 hr), and intracellular virus-specific RNA was determined by hydridization with complementary DNA. The steady-state concentration of virus-specific RNA was 1.7 times greater in IF-treated cells than in untreated cells. This suggests that virus-specific RNA synthesis continues after IF treatment and that the increased level of virus-specific RNA may result from the failure of virus particles containing virion RNA to bud from the cell surface. This suggestion was tested by determining the rate of virus-specific RNA synthesis (ie, the hybridization of pulse-labeled nuclear RNA) in treated and untreated cells. The fraction of labeled virus-specific RNA was approx equal in both cell groups. Thus, virus-specific RNA synthesis continued at approx normal rates in IF treated mouse cells chronically infected with M-MuLV. The data support the conclusion that the primary site of the action of IF on MuLV producer cells is at virus assembly. (18 refs)

78-3982 **Size Analysis and Relationship of Murine Leukemia Virus-specific mRNA's: Evidence for Transposition of Sequences During Synthesis and Processing of Subgenomic mRNA.** (Eng) Fan, H. (Tumor Virology Lab., Salk Inst., San Diego, CA, 92112); Verma, I. M. *J Virol* 26(2): 468-478; 1978.

Virus-specific messenger RNA (mRNA) from purified polyribosomes of mouse cells infected with Moloney murine leukemia virus (M-MuLV) was analyzed by electrophoresis in agarose gels, followed by hybridization of gel slices with M-MuLV-specific complementary DNA (cDNA). Two virus-specific mRNA's of 38S and 24S were detected. The 38S virus-specific mRNA, which is extremely similar if not identical in size to virion 38S RNA, contained the nucleotide sequences for all three M-MuLV structural genes. The 24S virus-specific mRNA was predominantly derived from the 3 half of the M-MuLV genome, since cDNA-*gag(pol)* (complementary to the 5′ half of the M-MuLV genome) could not efficiently anneal with this mRNA. Sequences complementary to cDNA synthesized from the extreme 5′ end of M-MuLV 38S RNA (cDNA 5′) were present in the 24S virus-specific mRNA, since cDNA 5′ (130 nucleotides) efficiently annealed with this mRNA. The annealing of cDNA 5′ was not due to repetition of 5′ terminal nucleotide sequences at the 3′ end of M-MuLV 38S RNA. The sequences in 24S virus-specific mRNA recognized by cDNA 5′ were not present in 3′ fragments of virion RNA that were of the same length. Therefore, it is suggested that RNA sequences from the extreme 5′ end of the M-MuLV genome may be transposed to sequences from the 3′ half of the M-MuLV 38S RNA during synthesis and processing of the 24S virus-specific mRNA. (36 refs)

78-3983 **Interstrain Variation of the Major Internal Structural Component (p30-gag) of Two Murine Oncornaviruses: Comparative Immunochemical, Biochemical, and Biophysical Analysis.** (Eng) Burnette, W. N. (Fred Hutchinson Cancer Res. Center, Seattle, WA, 98104); Mitchell, W. M. *J Virol* 26(2): 522-531; 1978.

The biophysical and biochemical properties of the major internal structural protein (p30-gag) of Moloney murine leukemia virus and endogenous Y-1 murine oncornavirus were compared. Although the two viral proteins share murine group-specific antigenic determinants, the Y-1 virus p30 appeared to have both a lower relative number of these determinants and a decreased affinity at the cross-reactive sites for Moloney virus p30 monospecific antibodies. Immunological analysis indicated the presence of unique antigenic sites on the Moloney virus p30 not shared by the analogous Y-1 virus molecule. The two polypeptides copurified and had similar isoelectric points (pH 6.2-6.3) and sedimentation coefficients (2.47S). However, equilibrium sedimentation yielded a significant mass difference, 28,300 daltons for the Moloney virus protein and 31,000 daltons for the Y-1 virus protein. Amino acids analysis indicated a concomitant increase in total residues for the Y-1 virus, p30, although a number of residues appeared to have been conserved between the two proteins. Conformational studies and hydrodynamic calculations indicated secondary and tertiary structural differences between the proteins. Two-dimensional mapping of the ^{125}-I-labeled tryptic peptides of each p30 suggested that considerable sequence heterogeneity is responsible for many of the biophysical, biochemical, and immunochemical differences between the two. (47 refs)

78-3984 **Viruses, Human Leukemias and Sarcomas.** (Eng) Boiron, M. (Lab. Experimental Hematology, Institut de Recherches sur les Leucemies, Hopital Saint-Louis, 75010 Paris, France). *In: Characterization and Treatment of Human Tumours. Proceedings of the Seventh International Symposium on the Biological Characterization of Human Tumours held in Budapest, April 13-15, 1977.* Davis, W.; Harrap, K. R., eds. (Amsterdam: Excerpta Medica): Advances in Tumour Prevention, Detection and Characterization. Vol. 4, 332 pp.; 3-6; 1978.

Complementary DNA (cDNA) probes were prepared using Moloney murine sarcoma virus(murine leukemia virus) [M-MSV(MuLV)] and simian sarcoma virus(simian sarcoma murine-associated virus) [SSV(SSAV)] and used to investigate human leukemias. In the first experiment, bone marrow cells, buffy coats, and continuous human cell lines from 46 leukemia cases and 10 controls were examined using the murine probe. Hybrids were identified in 22 of the leukemia cases and in none of the controls. Positive cases were found in all the different categories of leukemia, with the exception of chronic myeloid leukemia. Although hybridization rates were highly variable, some samples had hybridization levels similar to that of M-MSV(MuLV) RNA. In a second experiment, 12 leukemias and 4 controls were studied using both probes. There was a certain correlation between the two probes with respect to the positivity or negativity of the results, but this correlation was far from absolute. Some cases that were negative with the simian probe were positive with the murine probe and vice versa. The human RNA sequences detected by the two probes were shown to be unrelated. These results indicate that MSV- and SSV-like sequences are found in human DNA in addition to baboon endogenous virus (BEV)-like sequences. These findings, taken together with previous ones, suggest that all human tissues contain an endogenous provirus distantly related to BEV and that in certain leukemia patients, two independent sets of oncor navirus-related sequences (one related to murin oncornaviruses and another related to BEV) are present i the DNA. Sequences related to SSV-gibbon ape leukemi virus may be present in the cytoplasm of leukemic cells, bu they are not found in the DNA. (no refs)

78-3985 **The Effect of Mouse Interferon on the Transformation of NIH/3T3 Mouse Cells by Murin Sarcoma Virus.** (Eng) Morris, A. G. (Dept. Biologica Sciences, Univ. Warwick, Coventry, CV4 7AL, England) Clegg, C. *Virology* 88(2): 400-402; 1978.

The effect of interferon (IF) on the transformation of mous NIH/3T3 cells by the Kirsten strain murine sarcoma viru (MSV) was studied at various low multiplicities of infection Two assays of MSV transformation independent of virus replication were used: focus formation under conditions i which foci developed from cells infected with MSV alone an colony formation in agar suspension medium. Pretreatmen of cells with purified IF (10^4 units/ml) inhibited transformation upon infection with MSV by about 90%. Reconstructio experiments indicated that IF treatment did not block focu or colony formation by cells already stably transformed b MSV. If inhibited transformation per se, and not virus replication and spread. These findings indicate that there is a IF-sensitive step early in transformation. (11 refs)

78-3986 **Nucleases and Adenosine 3′,5′-Cyclic Monophosphate Phosphodiesterase Activities in Murine Sarcoma Virus (Moloney)-infected Mice.** (Eng) Tsou K. C. (Harrison Dept. Surgical Res., Sch. Medicine, Univ Pennsylvania, 1515 Ravdin Inst., 3100 Spruce St., Philadelphia, PA, 19101); Herberman, R. B. *J Natl Cancer Ins* 61(4): 1077-1083; 1978.

To provide information on the role of nucleases in oncogeni virus infection, the activities of 3′-nucleotide phosphodiesterase (3′-NPDase), 5′-nucleotide phosphodiesterase (5′ NPDase), acid deoxyribonuclease (DNase II), and 3′,5′ cyclic AMP phosphodiesterase (cAMPDase) in spleen extracts of murine sarcoma virus-infected C57BL/6 inbre mice were studied. Mice were inoculated im in the thigh region with 0.05 ml of a 1:20 dilution of the virus extract (x 10^6 focus-forming units/ml). This treatment produced tumors at the inoculation site in all recipients. At the peak o tumor growth and of the cell-mediated cytotoxic (CMC) response against tumor-associated antigens, 3′-NPDase, 5′ NPDase, and DNase II all showed depressed activities in th spleen, whereas the activity of cAMPDase increased at th peak of the CMC response and remained elevated thereafter Serum enzyme activities of the infected mice were also determined, and only 3′-NPDase in serum correlated well with th CMC response. Inasmuch as the correlation of tumor growt with the CMC response was established in this system, further study of tumors with variance between CMC and growt is necessary to determine if serum 3′-NPDase is a useful biochemical marker for the CMC response in vivo. (62 refs)

78-3987 **New Type B Retrovirus Isolates Associated with Kinetochores and Centrioles of the Host Cell.** (Eng) Heine, U. I. (Lab. Viral Carcinogenesis, NCI, Bethesda, MD, 20014); Todaro, G. J. *J Gen Virol* 39(1): 41-52; 1978.

Two new virus isolates, M432 and M832, obtained from the Southeast Asian mouse were characterized with respect to their ultrastructural composition and intracellular assembly. These viruses can be differentiated morphologically from each other by the structure of their virus envelopes, both in ultrathin sections and in negatively stained virus preparations. The mature virions resemble in certain respects the B-type murine retroviruses. The new isolates, however, have an intracellular precursor, an A-type particle, closely associated with the mitotic apparatus. The intracellular transport of the A-type particles to the cell surface, where they are released by budding, is closely associated with the microtubule system of the cell. The data also give evidence, for the first time, that virions belonging to the family of Retroviridae can be related to centriole-associated virus precursors. Since centrioles are known to be self-replicating organelles, it is speculated that this association could represent a possible mechanism for the vertical transmission of these viruses. (21 refs)

78-3988 **Presence of a Mouse Mammary Tumor Virus-related Antigen in Human Breast Carcinoma Cells and Its Absence from Normal Mammary Epithelial Cells.** (Eng) Yang, N. S. (Dept. Biology, Michigan Cancer Foundation, 110 E. Warren Ave., Detroit, MI, 48201); McGrath, C. M.; Furmanski, P. *J Natl Cancer Inst* 61(5): 1205-1208; 1978.

The human breast cancer cell line MCF-7 and normal human mammary epithelial cells were assayed for the presence of murine mammary tumor virus (MuMTV)-related antigen(s). Antigen(s) related to the major external glycoprotein (gp52) of MuMTV was found by immunofluorescence assays in the MCF-7 cells and in MuMTV producer cells, but not in any of the normal human mammary epithelial cells. Some of the primary cultures of cells from normal donors were treated with progesterone (10^{-8} M) and/or dexamethasone (10^{-5} M) prior to immunoassay. These hormones, which have been shown to stimulate MuMTV expression markedly in mouse tumor cells and to enhance the production of MuMTV-related antigens in MCF-7 cells, did not change the negative response of the normal human breast cells to anti-MuMTV sera. Even though normal human breast cells may contain virus particles, these particles are apparently not related to MuMTV. (25 refs)

78-3989 **Type B and Type C RNA Tumor Virus Replication in Single Cells. Electron Microscopy with Tannic Acid.** (Eng) Schidlovsky, G. (Medical Dept., Brookhaven Natl. Lab., Upton, NY, 11973); Shibley, G. P.; Benton, C. V.; Elser, J. E. *J Natl Cancer Inst* 61(1): 91-95; 1978.

Cells of a murine mammary tumor cell line (Mm5mt/c_1) were treated with tannic acid during specimen preparation, and thin sections were examined by electron microscopy. Simultaneous replication of murine mammary tumor virus (MuMTV; B-type) and murine leukemia virus (MuLV; C-type) was demonstrated along continuous stretches of the plasma membrane of single cells. The tannic acid treatment permitted improved discrimination between the B- and C-type virus in the thin sections. The B-type surface spikes were shown to be a homogeneous band of intermediate density and constant width on the bud surfaces, but the C-type buds had relatively smooth, spike-free envelopes. Both B- and C-type buds may contain morphologically identical horseshoe-shaped nucleoids, and, therefore, discrimination between the types must be made by ascertaining the presence or absence of characteristic spikes on the surfaces of the virus buds. The results show that complete replication of MuMTV and MuLV particles can occur simultaneously in the same host cell. (25 refs)

78-3990 **Mouse Mammary Tumor Virus and Murine Leukemia Virus Cell Surface Antigens on Virus Producer and Nonproducer Mammary Epithelial Tumor Cells.** (Eng) Schochetman, G. (Viral Oncology Program, Frederick Cancer Res. Center, Frederick, MD, 21501); Fine, D. L.; Massey, R. J. *Virology* 88(2): 379-383; 1978.

Mouse mammary tumor virus (MMTV)- and murine leukemia virus (MuLV)-specific cell-surface antigens (CSA) on virus producer and nonproducer mammary epithelial tumor cells were studied. The techniques used included lactoperoxidase-catalyzed iodination of cell surface proteins followed by radioimmune precipitation with monospecific antisera to the major MMTV (gp52, gp36, p27, and p10) and MuLV (gp70 and p30) proteins. The incorporation of iodinated CSA into extracellular virus was determined by analyzing labeled proteins in purified virus. Both gp52 and gp70 were present on the surface of cells producing only MMTV. Furthermore, gp52 was the only labeled protein in extracellular MMTV produced by these cells. On cells producing MMTV and MuLV, both gp52 and gp70 were present on the cell surface, and they were the only labeled proteins present in their respective extracellular viruses. This indicates that gp70 and gp52 were present on mutually exclusive cellular viral budding sites. In addition, MuLV anti-p30 serum precipitated two iodinated proteins with mol wts of 85,000 and 95,000 daltons, analogous to the Gross CSA. Since labeled gp52 and gp70 were also present on the surface of cells producing no virus but producing large amounts of MMTV glycoproteins and nonglycoproteins, they represent true CSA. These results show that the precursor to the MMTV glycoproteins (gPr75-MMTV *env*) is cleaved prior to the appearance of gp52 on the cell surface. (28 refs)

78-3991 **Immunological Characterization of the Low-Molecular-Weight DNA Binding Protein of Mouse Mammary Tumor Virus.** (Eng) Arthur, L. O. (Viral Oncology Program, Frederick Cancer Res. Center, Frederick, MD); Long, C. W.; Smith, G. H.; Fine, D. L. *Int J Cancer* 22(4): 433-440; 1978.

The purification of p14, the low-mol wt DNA-binding protein of mouse mammary tumor virus (MMTV), and its immunological properties are discussed. This protein was purified to homogeneity by guanidine-agarose chromatography followed by affinity chromatography on single-stranded DNA sepharose. Analysis of DNA-binding fractions by sodium dodecyl sulfate-polyacrylamide gel electrophoresis revealed a polypeptide of 14,000 daltons. Immunoprecipitation assays showed that MMTV p14 shared no cross-reactivity with gp52, gp36, or p10, antigens associated with the MMTV envelope, or with p27, which is found in the virion core. MMTV p14 did not cross-react with the low-mol-wt DNA-binding proteins of murine leukemia virus (MuLV). Cross-reactivity was observed between p14 and intracytoplasmic A particles, supporting the concept that A particles are morphological precursors to MMTV cores. Shared antigenic determinants were also demonstrated between intracytoplasmic A particles and MMTV p27, p20, and p10. p14 did not show cross-reactivity with the low-mol-wt DNA-binding proteins of C- or D-type viruses of higher mammals (Mason-Pfizer monkey virus, squirrel monkey retrovirus, baboon leukemia virus, AKR MuLV, and equine infectious anemic virus) in competitive radioimmunoassays. These results indicate that MMTV p14 is immunologically distinct from other MMTV proteins as well as from the DNA-binding proteins of other retroviruses. (29 refs)

78-3992 **Prevalence of Murine Mammary Tumor Virus Antibody and Antigens in Normal and Tumor-bearing Feral Mice.** (Eng) Fine, D. L. (Viral Oncology Program, NCI Frederick Cancer Res. Center, P.O. Box B, Frederick, MD, 21501); Arthur, L. O.; Gardner, M. B. *J Natl Cancer Inst* 61(2): 485-491; 1978.

Normal and tumor-bearing feral mice (*Mus musculus*) from three southern California areas, Asian *Mus* species, and *M. musculus* subspecies were studied to determine whether they possess antibody (Ab) to murine mammary tumor virus (MuMTV) or MuMTV-related antigens, particularly MuMTV gp52. Mice from Lake Casitas (LC) and La Puente (LP), California, have a high spontaneous lymphoma incidence, mice from Bouquet Canyon (BC) a low incidence. Radioimmunoassay showed that approx 20% of LC, LP, and BC mice expressed gp52 in specific tissues and that the organ distribution, predominantly in submaxillary glands and seminal vesicles (in addition to LC mammary tumors), was similar to that observed in inbred strains and did not differ with trapping location. In a radioimmune precipitation assay using ^{125}I-labeled MuMTV, only 6% of LC, LP, and BP mice contained precipitating Ab to MuMTV. Although moderate to high levels of gp52 were expressed in mammary tumor tissues of 3/7 LC and 3/3 (B10 x LC)F$_1$ mice, these animals showed no detectable MuMTV-precipitating Ab. Neither MuMTV Ab nor gp52 was detected in 10 lymphoma-bearing and 5 hepatoma-bearing LC mice. Low levels of MuMTV Ab and gp52 were detected in three *M. musculus* subspecies and in the Asian species *M. cervicolar*. Compared with normal and tumor-bearing inbred mice of high (C3H/HeN) and low (C3H/HeNf) mammary tumor strains, normal and tumor-bearing feral mice expressed low frequencies of MuMTV Ab and gp52. (39 refs)

78-3993 **Mapping of Linear and Circular Forms of Mouse Mammary Tumor Virus DNA with Restriction Endonucleases: Evidence for a Large Specific Deletion Occurring at High Frequency During Circularization.** (Eng) Shank, P. R. (Dept. Microbiology, Univ. California, San Francisco, CA, 94143); Cohen, J. C.; Varmus, H. E.; Yamamoto, K. R.; Ringold, G. M. *Proc Natl Acad Sci USA* 75(5): 2112-2116; 1978.

Linear and circular forms of unintegrated viral DNA were isolated from rat hepatoma cells infected with the GR strain of mouse mammary tumor virus. A DNA transfer procedure was then used to prepare restriction endonuclease fragment maps of these viral DNA forms. According to these maps: (1) the major species of viral DNA is a linear molecule (mol wt 5.9 x 10^6 daltons); located in the cytoplasm; (2) the nuclei contain covalently closed circular viral DNA of two distinct sizes (5.1 x 10^6 and 5.9 x 10^6 daltons) in addition to linear molecules (5.9 x 10^6 daltons); (3) the linear molecule has specific termini; (4) there is extensive homology between regions at or near termini of the linear molecule; (5) the predominant form of circular DNA lacks the 1.2 kilobase pairs present in the larger circular molecule and the linear molecule; (6) sequences deleted from most of the circular DNA molecules are located at the ends of the linear DNA that are joined during circularization. (24 refs)

78-3994 **Lysine tRNA Is the Predominant tRNA in Murine Mammary Tumor Virus.** (Eng) Waters, L. C. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830). *Biochem Biophys Res Commun* 81(3): 822-827; 1978.

The transfer RNA's (tRNA's) of mouse mammary tumor virus (MMTV) isolated from AKR mouse fibroblasts grown in vitro and from the milk of RIII mice were characterized. In both systems, lysine tRNA was the major tRNA in both the "free" 4S RNA and the "70S-associated" 4S RNA. The amount of lysine tRNA associated with the 70S RNA of MMTV was essentially the same as that reported for proline tRNA in AKR murine leukemia virus. (15 refs)

8-3995 **Type C Virus Replication and Expression in Human Rodent Hybrid Cells.** (Eng) Gazdar, A. . (NCI, Bethesda, MD, 20014); Edgell, C. J.; Oie, H. K.; .ussell, E. K.; Brown, S.; Lalley, P.; Minna, J. D. *In: Ad-ances in Comparative Leukemia Research 1977. Proceedings f the VIIIth International Symposium on Comparative Re-earch on Leukemia and Related Diseases, held in Amster-'am, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Iilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Iolland Biomedical Press): 503 pp.; 238-239; 1978.

Iuman cells were infected with baboon M7, feline xenotrop-:, and woolly monkey nontransforming component viruses, ised with nonpermissive mouse cells, and studied for virus eplication. The mouse genome suppressed the production of ll three viruses in the hybrid cells. The M7 virogene was not ompletely eliminated as human chromosomes were lost. 'urther studies indicated that the mouse cells restricted virus utput but not virus entry or integration. It appeared that uman chromosome 19 and possibly, chromosome 3 are es-ential for M7 replication. (no refs)

78-3996 **Macromolecular Synthesis in Cells Infected by Frog Virus 3. IX. Two Temporal Classes of Early Viral RNA.** (Eng) Willis, D. B. (Div. Virology, St. Jude Children's Hosp., P. O. Box 318, Memphis, TN, 38101); Granoff, A. *Virology* 86(2): 443-453; 1978.

By selectively inhibiting functional viral protein synthesis with cycloheximide (CX) or fluorophenylalanine (FPA) and analyzing the resultant viral RNA's by polyacrylamide gel electrophoresis and hybridization, early frog virus 3 (FV3) RNA could be subdivided into two sequentially synthesized classes. The polyacrylamide gel pattern of viral RNA synthesized 6 hr postinfection (PI) in FPA-treated cells was identical to that of the RNA synthesized at 1 hr PI in the absence of drug. RNA synthesized at 6 hr PI in the presence of FPA hybridized to 36% of the viral genome, but RNA synthesized 6 hr PI in its absence contained many additional species and hybridized to 50% of the genome. Therefore, the FPA RNA's appeared to represent the same sequences as the early viral RNA. In contrast, viral RNA's synthesized when protein synthesis was inhibited by cycloheximide (CX) did not contain all of the species present at 1 hr PI or in FPA RNA. The CX RNA's which hybridized to only 16% of the genome, comprised a subset of the FPA RNA's. One of the viral RNA species was synthesized at a much higher rate in CX-exposed cells than during infection in the presence or absence of FPA. When the addition of CX was delayed until 1 or 2 hr PI, all the remaining early viral RNA species were synthesized, and the rate of synthesis of the overproduced RNA decreased. Therefore, FV3 early RNA synthesis can be divided into two temporal classes: "immediate early", which occurs in the absence of protein synthesis CX and "delayed early", which occurs under conditions of restricted protein synthesis (FPA). The data also suggest that at least one species of immediate early viral RNA was subject to negative transcriptional control. (19 refs)

78-3997 **A Portion of the Feline Leukaemia Virus Genome Is Not Endogenous in Cat Cells.** (Eng) Okabe, H. (Viral Oncology Program, Frederick Cancer Res. Center, Frederick, MD, 21501); duBuy, J.; Gilden, R. V.; Gardner, M. B. *Int J Cancer* 22(1): 70-78; 1978.

An attempt was made to distinguish the feline leukemia virus (FeLV)-related sequences in normal cat cell DNA from those of FeLV-infected cellular DNA. Total ^{3}H-complementary DNA (^{3}H-cDNA) transcripts, prepared by viral endogenous reverse transcriptase reactions, were first annealed with excess DNA from normal cat liver (CL) under relaxed conditions. The portion remaining single-stranded after exhaustive hybridization was isolated and further purified by reannealing with the homologous viral 70S RNA. These cDNA probes, termed ^{3}H-cDNA(-CL), were used in hybridization kinetic analyses with cellular DNA from various sources. This probe could clearly distinguish virus-infected cells from noninfected cells by both hybridization extent and melting profiles of the resulting hybrids. It was found that (1) a portion of the genome of FeLV is not endogenous in normal cat cell DNA, and (2) this portion is found in cells and tissues that contain the virus. The same approach using the recycled ^{3}H-cDNA(-CL) of RD114 virus, another endogenous feline virus, failed to show any difference between a virus-infected cell line and normal cells, including both virus-inducible and noninducible lines. This finding suggests that the procedures are specific for FeLV. (33 refs)

78-3998 **Abrogation of Lymphocyte Blastogenesis by a Feline Leukaemia Virus Protein.** (Eng) Mathes, L. E. (Dept. Veterinary Pathobiology, Ohio State Univ., 1925 Coffey Road, Columbus, OH, 43210); Olsen, R. G.; Hebebrand, L. C.; Hoover, E. A.; Schaller, J. P. *Nature* 274(5672): 687-689; 1978.

The cause of the lymphocyte unresponsiveness (decline in cell-mediated immunity with no decline in circulating T cells) accompanying feline leukemia virus (FeLV) infection in cats was investigated. Purified p15 and p27 (the 15,000- and 27,000-mol wt structural proteins of FeLV) were tested for their inhibitory effect on the concanavalin A-lymphocyte blastogenesis (Con A-LBT) response of lymphocytes from normal, specific-pathogen-free cats. Addition of purified p15 reduced the Con A-LBT response by 45%-92% of that obtained with control cultures free of p15. p15 was inhibitory at concentrations ≥0.2 μg/well. Addition of p27 had no effect. Further studies indicated that addition of p15 had no effect on lymphocyte viability, it was not toxic to Con A-stimulated cells, and it was not a competitive inhibitor of Con A binding. These findings suggest that p15 is the mediator of FeLV-associated lymphocyte unresponsiveness. (20 refs)

78-3999 **Influence of Thymectomy on the Susceptibility of Cats to Feline Leukemia Virus and Lymphosarcoma.** (Eng) Hoover, E. A. (Dept. Veterinary Pathobiology, Ohio State Univ., Columbus, OH, 43210); Krakowka, S.; Cockerell, G. L.; Mathes, L. E.; Olsen, R. G. *Am J Vet Res* 39(6): 993-995; 1978.

Of 12 cats thymectomized at age 5 wk, 6 were inoculated at age 8 wk and 6 at age 4 mo with the Rickard strain of feline leukemia virus (FeLV-R), which produces a high incidence of thymic lymphosarcoma (LSA). The cats received 1.0 ml of an inoculum containing 10^3 focus-forming units of FeLV infectivity. Two groups of age-matched nonthymectomized cats were inoculated with the same FeLV-R stock. Thymectomy prior to FeLV infection had no influence on the induction of viremia or LSA incidence. In the FeLV-inoculated nonthymectomized group, two cats developed thymic LSA. In the thymectomized group, three cats developed LSA in the intestine, mesenteric lymph nodes, or bone marrow, but the malignant lymphoblasts had surface markers characteristic of feline T lymphocytes. It is concluded that the presence of the thymus per se is not required for infection and oncogenesis by FeLV and that feline T lymphocytes may be transformed after peripheralization to other tissues. (28 refs)

78-4000 **Differential Growth and Transmission in Cats of Feline Leukaemia Viruses of Subgroups A and B.** (Eng) Jarrett, O. (Dept. Veterinary Pathology, Veterinary Sch., Univ. Glasgow, Bearsden, Glasgow G61 1QH, Scotland); Russell, P. H. *Int J Cancer* 21(4): 466-472; 1978.

Cats were infected with feline leukemia virus (FeLV) of subgroups A (FeLV-A) or B (FeLV-B), and the course of infection was followed. After FeLV-A infection, virus was quickly recovered from the blood and oropharynx of most animals. Following infection with FeLV-B, only a small proportion of cats developed a viremia and then only after a long interval. There was no evidence that FeLV-B was transmitted by contact. In cats infected with mixtures of FeLV-A and -B (FeLV-AB), each virus operated independently. In a high proportion of the cats, but not in all cats, FeLV-A was recovered from the plasma first and FeLV-B appeared later. There was evidence of interaction, however, in that the proportion of cats that were viremic with FeLV-B was greater following FeLV-AB infection than after infection with FeLV-B alone. FeLV-B was transmitted by contact from cats excreting FeLV-AB. These results help to explain the apparent dependence of FeLV-B on FeLV-A under natural conditions and the frequency of occurrence of subgroups A and B in FeLV isolates. It is suggested that the differences between FeLV-A and FeLV-B may be caused by each virus infecting a different cell population. (19 refs)

78-4001 **Immunological Nature of the Inhibition of BLV-induced Early Polykaryocytosis by Bovine Sera.** (Eng) Astier, T. (Groupe d'Etude de la Leucose Bovine, Institut National de la Sante et de la Recherche Medicale, Unite de Recherches de Radiobiologie Experimentale, de Cancerologie U-117, 229 cours de l'Argonne, 33076 Bordeaux, France); Mamoun, R.; Guillemain, B.; Parodi, A. L.; Duplan, J. F. *Int J Cancer* 22(1): 47-54; 1978.

A quantitative in vitro assay, the early polykaryocytosis inhibition (EPI) test, was developed for the serological detection of bovine leukemia virus (BLV) infection in cattle. The EPI assay is based on the inhibition by bovine sera of syncytia formation in mixed cultures of BLV-infected fetal lamb kidney cells and mouse sarcoma virus-infected feline cells. These investigations were concerned specifically with characterizing the EP-inhibiting factor. The immunoglobulin (Ig) nature of the factor was demonstrated by its high mol wt, its sensitivity to digestion with proteinase-K but not RNase or DNase, and by studies ruling out the participation of serum complement or interferon. Removal of Ig's from positive serum fractions completely destroyed the EP-inhibiting ability. Serum fractionation by gel filtration and affinity chromatography indicated that EP-inhibiting activity is mediated only by Ig's of the IgG class. These antibodies were classified as IgG1 by ion-exchange chromatography. Although the fundamental mechanism of EP has not been clarified completely, the EPI technique, because of its specificity for BLV and its high sensitivity, can be adapted to large-scale seroepidemiological surveys in cattle. (20 refs)

78-4002 **Analysis of Human Diploid Cell Cultures for the Presence of Oncornavirus Determinants.** (Rus) Stepanova, L. G. (No affiliation given); Andzhaparidze, O. G.; Avakova, A. N.; Liozner, A. L.; Mel'nikova, N. L.; Korchak, O. B.; Lotte, V. D.; Shukhmina, N. R.; Rozina, E. E. *Vopr Virusol* (2): 170-176; 1978.

The expression of primate leukemia virus (PLV) was assayed in various strains of human diploid cell cultures (human embryo lung cells: WI-38, and strains L-58 and L-63). The assays included determination of reverse transcriptase activity, molecular hybridization, evaluation of infectivity in a KC test, immunodiffusion, immunofluorescence, and evaluation of tumorigenicity in Syrian hamsters. During passage in the second to third growth phases, all three diploid cell cultures retained the morphological and karyological characteristics of normal fibroblasts. The cultures were found to be free of oncornavirus particles or virus-specific antigens. Transitory tumorigenicity was recorded only in the 44th passage of strain L-63. L-58 strain cells were tumorigenic in hamsters at passages 27 and 43; subsequent passages were not tumorigenic. (15 refs)

78-4003 **Hepatitis B Surface Antigen and Primary Liver Cancer.** (Eng) Van Den Heever, A. (Dept. Internal Medicine, H. F. Verwoerd Hosp., Privale Bag X169, Pretoria, 0001, Republic S. Africa); Pretorius, F. J.; Falkson, G.; Simson, I. W. *S Afr Med J* 54(9): 359-361; 1978.

The incidence of hepatitis B surface antigen (HBsAg) was determined in the sera of 92 black patients with primary liver cancer (PLC) and 92 matched controls with no history of liver disease. Sera from 31 PLC patients and 8 controls were positive for HBsAg; this difference was significant ($p < 0.01$). Associated liver disease was diagnosed in 56 PLC patients. Of these patients, HBsAg was found in the sera of 8/36 patients with chronic Budd-Chiari syndrome, 6/9 with post-collapse cirrhosis, 1/9 with siderosis, and 0/2 with fibrosis. It is suggested that the pathogenesis of PLC has the following cycle: hepatitis B infection, cirrhosis, PLC. These findings combined with those in the literature suggest that the role of hepatitis B infection in the pathogenesis of PLC varies in different geographical areas. (23 refs)

78-4004 **Virus-specific Markers and Virus-like Particles in Cell Lines of Tumors Produced by CELO Virus in Syrian Golden Hamsters.** (Eng) Asch, B. B. (Dept. Cell Biology, Baylor Coll. Medicine, Houston, TX, 77030); McCormick, K. J.; Stenback, W. A.; Trentin, J. J. *J Natl Cancer Inst* 61(1): 163-171; 1978.

Five cell lines were established from chicken embryo lethal orphan (CELO) virus-induced hamster tumors and examined for the presence of CELO virus-specific markers and hamster viruslike particles (VLP). Two of the cell lines were derived from primary hepatocellular carcinomas (HCC) arising in CELO virus-inoculated LSH/Lak inbred hamsters and three from sarcomas that developed in CELO virus-inoculated outbred hamsters. Cell lines from two of the sarcomas (COT and CMT) and one HCC (CEHEP) produced CELO virus-specific tumor (T) antigen. The antigen was not detected in cells of the third sarcoma line (RCT) until they had undergone >34 passages in vitro. Although 5%-10% of cells in the second HCC line (CILT/2) contained T antigen during early passages, it was not detected after the fifth subculture. Cells of both HCC lines possessed CELO virus tumor-specific transplantation antigen. All five cell lines also contained hamster R-type particles, and both HCC lines had C-type and intracytoplasmic A-type particles. The percentage of carcinoma cells producing R-type particles increased during cultivation in vitro, whereas the number of cells with A-type particles decreased. Treatment with dibutyryl cyclic AMP and theophylline enhanced the number of cells producing C-type particles in one HCC line and R-type particles in two of the sarcoma lines. This study provides no evidence that indigenous VLP of the hamster are more than passengers in CELO virus-induced tumors. CELO virus appear to be the primary etiologic agent. However, the host cell may exert a regulatory function on the expression of CELO virus-related markers. (49 refs)

78-4005 **Application of the Immuno-peroxidase Method to the Study of Tumor Viruses. 1. DNA Tumor Viruses.** (Eng) Imamura, M. (Dept. Pathology, Sapporo Medical Coll., Sapporo, Japan); Toh, K.; Ueno, H. *Tumor Res (Sapporo)* 12: 14-28; 1977.

The use of immunoperoxidase methods to study the ultrastructural localization of the cell-surface antigens of DNA tumor viruses is described. Although satisfactory and reproducible results were obtained, several technical problems remain to be settled, mainly dealing with cell fixation. (40 refs)

78-4006 **Membrane Alterations Associated with "Transformation" by BUdR in BUdR-Dependent Cells. Fluorescence Polarization Studies with a Lipid Probe.** (Eng) Rosenthal, S. L. (Div. Human Genetics, Children's Hosp. Medical Center and Dept., Microbiology and Molecular Genetics, Harvard Medical Sch., Boston, MA, 02115); Parola, A. H.; Blout, E. R.; Davidson, R. L. *Exp Cell Res* 112(2): 419-429; 1978.

Steady-state and nanosecond fluorescence polarization (FP) analyses were used to study the membrane fluidity of a bromodeoxyuridine (BUdR)-dependent cell line (B4) derived from a malignant Syrian hamster melanoma line. In the presence of BUdR, B4 cells resemble transformed cells. For comparison, the cells were also grown in the absence of BUdR (as 'untransformed' cells). Membrane fluidity was estimated from FP measurements of membrane lipids labeled with the fluorescent probe 1,6-diphenyl-1,3,5-hexatriene, a technique used previously to show that FP values differ between normal and malignant lymphocytes and between untransformed and virally transformed 3T3 cells. The steady-state FP values of the membrane lipids of B4 + BUdR cells were larger than those of the lipids of B4-BUdR cells; ie, the membranes of the 'transformed' B4 cells were less fluid than those of the 'untransformed' B4 cells. The change in FP values was found to be fully reversible. Nanosecond rotational correlation time experiments confirmed and extended these results. In view of the findings and those of previous studies, it is suggested that the membranes of the B4 + BUdR cells resemble those of virally transformed 3T3 cells and the membranes of B4-BUdR cells resemble those of untransformed 3T3 cells. Line B4 offers a unique opportunity for elucidating the metabolic alterations involved in malignant transformation. (23 refs)

78-4007 **Natural Transmission of Gibbon Leukemia Virus.** (Eng) Kawakami, T. G. (Comparative Oncology Lab., Univ. California, Davis, CA, 95616); Sun, L.; McDowell, T. S. *J Natl Cancer Inst* 61(4): 1113-1115; 1978.

The possible natural mode of transmission of gibbon ape leukemia virus (GaLV) was investigated. Transmission of infectious virus was based on the detection of humoral antibody, presence of infectious virus, or on molecular hybridization. It was found that GaLV can infect prenatal gibbons through in utero infection or postnatal gibbons through contact transmission. The transmission of infectious virus was from viremic gibbons and not from uninfected or antibody-positive animals. The two modes of transmission could be distinguished by the amount of proviral DNA integrated into the muscle tissue of viremic gibbons. Muscle of gibbons infected postnatally had little or no proviral DNA, whereas gibbons infected prenatally had a large quantity of proviral DNA. Examination of cellular DNA for provirus in 'nontarget' organs may be useful in establishing the natural mode of transmission of exogenous oncornaviruses. (18 refs)

78-4008 **The Major Core Protein of Mammalian Type C Viruses: Structural Comparisons of a Conserved Gene Product.** (Eng) Gautsch, J. W. (Scripps Clinic and Res. Foundation, La Jolla, CA, 92037); Elder, J. H.; Jensen, F. C.; Lerner, R. A. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 237; 1978.

The major core proteins of > 40 mammalian C-type viruses were mapped and (MuLV) p30's;, the p27's of the woolly monkey-gibbon ape viruses and a xenotropic mouse virus; and the p27's from baboon, cat, and rat C-type viruses formed three distinct structural groups. In addition, several structural subtypes of MuLV p30's were noted. The close relationship between the p27's of RD114 and M-7 viruses and the p27's of feline leukemia viruses and rat viruses suggests that they are of recent common origin. (no refs)

78-4009 **Natural Distribution of Squirrel Monkey Retrovirus Proviral Sequences in Primate DNAs.** (Eng) Schochetman, G. (Viral Oncology Program, Frederick Cancer Res. Center, Frederick, MD, 21501); Fine, D. L. *J Gen Virol* 40(part 1): 257-261; 1978.

The cellular DNA of various primates was examined for the presence of virus genes related to those present in squirrel monkey retrovirus (SMRV) by nucleic acid hybridization. ^{3}H-SMRV 70S RNA hybridized extensively to squirrel monkey DNA, whereas no significant hybridization above background was observed between SMRV and the DNA of New World monkeys (woolly monkey, capuchin, owl), Old World monkeys (rhesus, African green), apes (gibbon, chimpanzee), and humans (A204 human rhabdomyosarcoma cell line, uninfected or infected with Mason-Pfizer monkey virus). The hybridization conditions used would only detect highly conserved (perfectly matched) sequences. The extent of hybridization to the DNA'S of liver, kidney, and brain from two different squirrel monkeys ranged from 52% to 76%, and it correlated with the number of proviral sequences, as measured by the $C_0t1/2$ values. These values indicated that SMRV provirus was present in multiple copies (5-10) in these tissues. In contrast, a max of 30% hybridization was obtained with the DNA of SMRV-infected A204 cells, a result of the low number (1-2 copies) of proviral sequences present in these cells. These results demonstrate that SMRV is a new endogenous, vertically transmitted virus of squirrel monkeys and the first isolated from a New World primate. (13 refs)

78-4010 **Comparison of Mason-Pfizer Monkey Virus and Squirrel Monkey (*Saimiri sciureus*) Retrovirus by Immunoelectron Microscopy.** (Eng) Smith, G. C. (Southwest Foundation Res. and Education, P.O. Box 28147, San Antonio, TX, 78284); Heberling, R. L.; Kalter, S. S. *J Natl Cancer Inst* 61(2): 411-413; 1978.

Immunoelectron microscopy indicated that Mason-Pfizer monkey virus and squirrel monkey retrovirus (both candidate D-type oncornaviruses) do not share common surface antigens. In addition, there was no indication of cross-reactivity with baboon endogenous virus antiserum and the surface antigens of the two viruses. (16 refs)

78-4011 **Comparative Studies on Non-Type C Primate Retraviruses: Squirrel Monkey Virus (SMRV) from New World Monkeys and Mason-Pfizer Virus (MPMV) from Old World Monkeys.** (Eng) Fine, D. L. (Viral Oncology Program, NCI Frederick Cancer Res. Center, P.O. Box B, Frederick, MD, 21501); Schochetman, G.; Arthur, L. O.; Gilden, R. V. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 242-244; 1978.

Studies of the relationship between squirrel monkey virus (SMRV) from New World monkeys and Mason-Pfizer virus (MPMV) from Old World monkeys indicated that SMRV is antigenically distinct from various mammalian retraviruses and that it is present in multiple copies in the DNA of squirrel monkeys. According to hybridization experiments, SMRV is endogenous to squirrel monkeys and shares little sequence homology with MPMV. (5 refs)

78-4012 **Immunological and Structural Relationships Between Langur Virus and Other Primate Type-D Retroviruses.** (Eng) Colcher, D. (Lab. Viral Carcinogenesis, NCI, NIH, Bethesda, MD, 20014); Teramoto, Y. A.; Schlom, J. *Virology* 88(2): 384-388; 1978.

The major structural proteins of three D-type retroviruses, Mason-Pfizer monkey virus (MPMV) from rhesus monkeys, squirrel monkey retrovirus (SMRV), and langur retrovirus (LV), were compared using sodium dodecyl sulfate-polyacrylamide slab and tube gel electrophoresis and competitive radioimmunoassays (RIA's). Squirrel monkeys are a New World species, but the rhesus and langur monkeys are Old World species. The virion-associated polypeptides of LV and MPMV had indistinguishable electrophoretic mobilities in polyacrylamide gels. Homologous RIA's for the major 27,000-dalton structural protein (p27) of LV and for the p27 of MPMV also could not distinguish between these two viruses. LV and MPMV could be differentiated, however, by either of the RIA's developed for their 10,000- to 12,000-dalton proteins. The major structural protein of SMRV was more immunoreactive with LV than with MPMV. An interspecies RIA was also developed using antiserum to LV to precipitate ^{125}I-labeled MPMV p27. This assay was more effective than either of the homologous LV or MPMV RIA's for the recognition of SMRV, and it may be useful in detecting and characterizing new primate retrovirus isolates. (15 refs)

78-4013 **Biological and Biochemical Properties of a Human Oncornavirus System (PMF).** (Eng) Bierwolf, D. (Zentralinstitut fur Krebsforschung, Akademie der Wissenschaften der DDR, 1115 Berlin-Buch, E. Germany); Wunderlich, V.; Micheel, B.; Graffi, A. *In: Characterization and Treatment of Human Tumours. Proceedings of the Seventh International Symposium on the Biological Characterization of Human Tumours held in Budapest, April 13-15, 1977.* Davis, W.; Harrap, K. R., eds. (Amsterdam: Excerpta Medica): Advances in Tumour Prevention, Detection and Characterization. Vol. 4, 332 pp.; 38-47; 1978.

Virus particles that appeared in a human embryonic cell line obtained from the embryo of a woman who had generalized carcinoma of the cervix uteri were characterized. Morphological experiments indicated that the particles were considered a D-type oncornavirus (designated PMF virus) with a structure very similar to that of Mason-Pfizer monkey virus. Of several antisera tested, only antiserum to Mason-Pfizer monkey virus produced immunoprecipitation lines with the PMF virus or virus-containing cell extracts. Thus, these two types of viruses are closely related. Biochemical investigations indicated that both exogenous and endogenous reverse transcriptase (RT) activity is present in the virus particles. This RT required the presence of divalent cations and was preferentially activated by Mg++ rather than by Mn++. According to preliminary data obtained by gel electrophoresis, the virus contains the polypeptides p10, p16, p30, gp40, p49, and gp65. The data suggest that PMF virus is of human origin. (10 refs)

78-4014 **Type D Retroviruses: Occurrence of Natural Antibodies to Mason-Pfizer Monkey Virus in Rhesus Monkeys.** (Eng) Fine, D. L. (Viral Oncology Program, Frederick Cancer Res. Center, Frederick, MD, 21501); Devare, S. G.; Arthur, L. O.; Charman, H. P.; Stephenson, J. R. *Virology* 86(2): 567-571; 1978.

Sera of rhesus monkeys maintained in colonies at three separate geographic regions were found to possess naturally occurring antibody to the Mason-Pfizer monkey virus (MPMV) major structural protein, p26. The specificity of this reactivity was established by absorption with purified viral protein. Animals from two of the colonies were housed in association with MPMV-infected monkeys, but no such prior exposure to virus-infected animals could be traced in the case of the third colony. These results, in combination with previous inability to detect full complements of MPMV genetic sequences in the cellular DNA of normal rhesus monkeys, provide evidence for the horizontal transmission of MPMV. Alternatively, the present findings could reflect a humoral immune response to expression of an endogenous D-type retrovirus highly related to MPMV. (25 refs)

78-4015 **Simian Mason-Pfizer Virus-induced Chronic Infection in Primate Cell Cultures.** (Rus) Nosik, N. N. (D. I. Ivanovskii Inst. Virology, Moscow, USSR); Fain, D. L.; Priori, E. S.; Artur, L.; Gonda, M. S.; Plouman, D. T.; Ershov, F. I. *Vopr Virusol* (2): 165-169; 1978.

The expression of simian Mason-Pfizer virus (MPV) was studied in a *Macaca rhesus* prepuce cell culture (Rhfs), a transplantable culture of monkey kidney cells (BSC-1), and a primary culture of trypsinized human embryo kidney cell (HEK). Chronic infection with MPV was established in the Rhsf culture during the third passage. Characteristic features of chronic infection were the presence of virus-specific gs antigen in the perinuclear zone, polynuclear cells, and relatively high levels of RNA-dependent DNA-polymerase activity. Although the BSC-1 cells also showed enhanced DNA synthesis, they lacked polynuclear cells. The HEK culture was the least susceptible to the oncornavirus. There were no signs of transformation in any of the three cultures. (10 refs)

78-4016 **Structures of Polyoma Virus: On the Histone Component and Virion Core.** (Eng) Frost, E. (Montreal Cancer Inst., Notre Dame Hosp., 1560 Sherbrooke St. E., Montreal, Quebec H2Z 4K8, Canada); Bourgaux, P. *J Gen Virol* 39(1): 103-111; 1978.

Purified polyoma virus was able to take up an amount of calf thymus histone equivalent to 10%-50% of its normal histone content under conditions permitting the binding of considerably lesser amounts of several other proteins (myoglobin, ovalbumin, and bovine serum albumin). Some of the bound histone could not be released by procedures routinely used for virus purification. Some of the histone present in purified polyoma virus could be selectively released by detergent treatment without breakdown of virus particles. These observations suggest that a significant proportion of the histone of purified polyoma virus is either located on the surface of the virion or it can readily enter or leave the capsid. (35 refs)

78-4017 **Chromatographic Separation of the Polyoma Virus Proteins and Renaturation of the Isolated VP$_1$ Major Capsid Protein.** (Eng) Brady, J. N. (Div. Biology, Kansas State Univ., Manhattan, KS, 66506); Consigli, R. A. *J Virol* 27(2): 436-442; 1978.

Chromatography of 6 M guanidine hydrochloride-denatured polyoma virion proteins through Sepharose CL-6B beads allowed separation of the dimer, VP$_1$, VP$_2$, VP$_3$, and the histone proteins VP$_{4\text{-}7}$ in highly purified form. Renaturation of VP$_1$ resulted in the formation of subunits that were morphologically, biophysically, and immunologically similar to native virion capsomeres. (20 refs)

78-4018 **BK Virus DNA: Cleavage Map and Sequence Analysis.** (Eng) Yang, R. C. (Dept. Biochemistry, Cornell Univ., Ithaca, NY, 14853); Wu, R. *Proc Natl Acad Sci USA* 75(5): 2150-2154; 1978.

A detailed physical map of BK virus (MM strain) DNA was constructed with respect to the cleavage sites of 11 different restriction enzymes. The enzymes cut the DNA at 61 specific sites, the locations of which were determined. Preliminary nucleotide sequence analysis was performed in the region from 0.70 to 0.75 map units on the viral DNA. An 80% homology was found between 0.714-0.744 map units on BK virus DNA and 0.722-0.752 map units on simian virus 40 (SV40) DNA. This region of SV40 DNA codes for the synthesis of the leader sequence of late messenger RNA. It is likely that only part of this sequence constitutes specific recognition signals and is absolutely required. (27 refs.)

78-4019 **Failure to Demonstrate Papovavirus Tumor Antigen in Human Cerebral Neoplasms.** (Eng) Greenlee, J. E. (Dept. Neurology, Johns Hopkins Univ. Sch. Medicine, Baltimore, MD, 21205); Becker, L. E.; Narayan, O.; Johnson, R. T. *Ann Neurol* 3(6): 479-481; 1978.

Cell cultures established from 80 brain tumors (astrocytoma, meningioma, glioblastoma multiforme, medulloblastoma, ependymoma, and others) were examined by the fluorescent antibody technique for the presence of the intranuclear tumor (T) antigen common to cells transformed by simian virus 40 (SV40) or BK or JC viruses. Brilliant intranuclear fluorescence comparable to that seen in cells cultured from papovavirus-induced hamster cerebral tumors was not seen in any of the human brain tumor cells. A small number of cells from one meningioma showed faint nuclear fluorescence at early passages but not on subsequent passages. These results provide no support for the association of these primate papovaviruses with human cerebral neoplasms. (28 refs)

78-4020 **Brain Tumors in Owl Monkeys Inoculated With a Human Polyomavirus (JC Virus).** (Eng) London, W. T. (Infectious Diseases Branch, Natl. Inst. Neurological and Communicative Disorders and Stroke, Bethesda, MD, 20014); Houff, S. A.; Madden, D. L.; Fuccillo, D. A.; Gravell, M.; Wallen, W. C.; Palmer, A. E.; Sever, J. L.; Padgett, B. L.; Walker, D. L.; ZuRhein, G. M.; Ohashi, T. *Science* 201(4362): 1246-1249; 1978.

Adult feral owl monkeys (*Aotus trivirgatus*) were inoculated intracerebrally, sc, and iv with human JC (14 animals) or BK virus (4) or with simian virus 40 (SV40; 4 monkeys). Six JCV-inoculated monkeys received immunosuppressive doses of cyclophosphamide and prednisone for 10 wk before and 10 wk after JCV inoculation. One mo after inoculation, all JCV monkeys had antibody titers to JCV of 80-2,560 and BKV monkeys had antibody titers to BKV of 160-10,240, as determined by hemagglutination-inhibition. Antibody titers to SV40, as determined by plaque-reduction neutralization were 80-$\geq$160 in SV40 monkeys. Antibodies against tumor (T) antigen appeared in the serum of all virus-inoculated animals after 3-5 mo, and they were still detectable after 3 yr. Two of four surviving JCV monkeys developed brain tumors, one 16 mo and one 25 mo after inoculation. Neither monkey had been immunosuppressed. A Grade 3 to Grade 4 astrocytoma (resembling a human glioblastoma multiforme) was found in the left cerebral hemisphere and brainstem of one monkey. The second monkey developed a malignant tumor in the left cerebral hemisphere that contained both glia and neuronal cell types. Impression smears of the second tumor showed numerous cells containing intranuclear T antigen; virion antigens were not detected. Tumor cells cultured in vitro also contained T antigen, but they were negative for virus antigen. Infectious virus was not isolated from tumor extracts. These results suggest that the oncogenicity of JCV extends to nonhuman primates. (30 refs)

78-4021 **Effect of Inactivated Sendai Virus on Adsorption and Penetration of Polyoma Virus.** (Eng) Artamonova, V. A. (N. F. Gamaleia Inst. Epidemiology and Microbiology, Moscow, USSR); Shevliagin, V. I. *Vopr Virusol* (2): 187-192; 1978.

The effect of Sendai virus (SV) on the adsorption, elution, and penetration of oncogenic polyoma virus (PV) was studied in primary cultures of murine, chick, and human embryo fibroblast cultures. Within 3 hr of adsorption of ^{3}H-thymidine-labeled PV, the SV-treated permissive murine fibroblast culture contained approx 60% of radioactivity in the nuclear fraction. In the nonpermissive SV-treated chick and human fibroblast cultures, 46%-57% of the radioactivity was detected in the granular fraction but only 14% in the nuclear fraction. SV enhanced the penetration of PV only in the permissive culture. (8 refs)

78-4022 **Viral Sequences Related to a Human Skin Papillomavirus in Genital Warts.** (Eng) Orth, G. (Unite' de Recherches sur l'Etiologie Virale des Cancers Humains, U140 INSERM, LA147 CNRS, Institut Gustave-Roussy, 94800 Villejuif, France); Favre, M.; Jablonska, S.; Brylak, K.; Croissant, O. *Nature* 275(5678): 334-336; 1978.

Total DNA from the genital warts (condylomata acuminata) of seven patients as well as purified form I DNA preparations were hybridized with ^{3}H-labeled RNA's complementary (cRNA's) to four types of human papillomavirus (HPV-1, -2, -3, and -4) to determine whether the genital wart DNA had sequences homologous to HPV DNA. No significant hybridization was obtained with any of the genital wart DNA's (total or form I) and HPV-1, HPV-2, or HPV-3 cRNA's. However, all seven total DNA preparations as well as purified form I DNA from two patients showed significant levels (3.5%-8.8%) of hybridization with the HPV-4 cRNA probe. Thus, viral sequences related to HPV-4 are present in the DNA of the warts studied, but it is not known to what extent the sequences are related. (22 refs)

78-4023 **A Search for an Association Between Simian Virus 40 and Human Meningiomas.** (Eng) Cikes, M. (Ludwig Inst. Cancer Res., 1066 Epalinges, Switzerland); Beth, E.; Giraldo, G.; Acheson, N.; Hirt, B. *In: Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation.* Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 698 pp.; 1009-1011; 1977.

Twenty-four human meningiomas were examined for the presence of simian virus 40 (SV40) tumor (T) antigen. All tumors were negative by indirect immunofluorescence. In addition, RNA from the six tumors tested failed to hybridize with SV40 DNA, and extracts of 16 tumors were negative in complement fixation tests. Finally, no antibodies against the T antigens of SV40, JC, or BK viruses were detected in the sera of all 16 patients analyzed. (9 refs)

78-4024 **The Structure of Genes, Intergenic Sequences, and mRNA from SV40 Virus.** (Eng) Thimmappaya, B. (Dept. Human Genetics, Yale Univ. Sch. Medicine, New Haven, CT, 06510); Reddy, V. B.; Dhar, R.; Celma, M.; Subramanian, K. N.; Zain, B. S.; Pan, J.; Weissman, S. M. *Cold Spring Harbor Symp Quant Biol* 42(part 2): 449-456; 1978.

Analysis of the nucleotide sequence of simian virus 40 (SV40) DNA showed that the late proteins VP2 and VP3 are coded for by overlapping messages translated in the same reading frame. The initiator codon for VP3 may be a methionine codon within the gene for VP2. The codons for the carboxy-terminal amino acids of VP2 and VP3 were read in a second frame as the codons for the amino-termini amino acids of VP1. The largest continuous stretch of triplets in SV40 DNA that could be transcribed into sense codons included $<75\%$ of the early region, and it could only code for a protein of mol wt $<70{,}000$. This contrasted with the reported mol wt of the SV40 'A' protein of 70,000-94,000. Almost one-third of the SV40 DNA did not code simply for known proteins. The remaining DNA included sequences complementary to the untranslated 3′ ends of early and late messenger RNA (mRNA), sequences at the origin of DNA replication, reiterated sequences, and sequences that could potentially code for small polypeptides. One such sequence lies between the origin of replication and the initiator codon for VP2. The transcript of much of this DNA was abundantly represented in cytoplasmic polyadenylated RNA, but there appeared to be a short gap at 0.765 fractional genome length where little or no unmodified transcript was present in the cytoplasm. The sequence preceding 0.765 appeared to be covalently joined to the RNA sequence of transcripts of DNA beginning from 0.95 and onward. This composite RNA was the 16S mRNA that has been reported to direct the synthesis of VP1. (26 refs)

78-4025 **Polysomes and Polysomal mRNAs in SV40-infected CV-1 Cells. In Vivo Observations.** (Eng) Ho-Terry, L. (Dept. Bacteriology, Univ. Coll. Hosp. Medical Sch., University St., London WC1E 6JJ, England); Terry, G. M.; Cohen, A. *Biochim Biophys Acta* 519(2): 390-397; 1978.

The association of late simian virus 40 (SV40)-specific messenger RNA's (mRNA's) with polysomes in virus-infected (100 plaque-forming units/cell) African green monkey kidney CV-1 cells was examined. A comparison of polysomes in mock- and SV40-infected cells was made by labeling the cells with ^{3}H-uridine prior to their infection. Sucrose gradient centrifugation indicated that the polysomes from the virus-infected cells were heavier and UV absorbance indicated that they contained more ribosomes than the polysomes of mock-infected cells. Approx 40%-45% of the mRNA's on the polysomes of the infected cells were virus-specific. The mRNA's coding for the virion polypeptides VPI, II, and III synthesized per unit time was determined by measuring the radioactivity incorporated by them per minute. The ratio of VPI to VPII + III was 3.38:2.16. Since the 16S mRNA codes for VPI and the 19S mRNA codes for the other two polypeptides, the amount of these mRNA's associated with the polysomes was also determined. The 16S and 19S mRNA's were present in a ratio of 1.88:1.00, similar to the ratio obtained with the polypeptides. Thus, the relative amounts of virus-specific polypeptides synthesized in virus-infected cells is determined by the relative amounts of 16S and 19S mRNA's coding for them. (16 refs)

78-4026 **Cytogenetic Studies of a Simian Virus 40 Temperature-sensitive Mutant-transformed Chinese Hamster Cell Clone at the Permissive and Nonpermissive Temperature.** (Eng) Lehman, J. M. (Dept. Pathology, Univ. Colorado Medical Center, 4200 E. Ninth Ave., Denver, CO, 80262); Robinson, C. C. *J Natl Cancer Inst* 61(4): 1171-1174; 1978.

A clone of Chinese hamster embryo cells transformed by tsA58, the temperature-sensitive mutant of simian virus 40, was analyzed for chromosome abnormalities at the permissive temperature (37 C) and nonpermissive temperature (40.5 C). The cells of this clone, A58/1, were grown at 37 C for 1 day; then one bottle was shifted to 40.5 C and subcultured (2 passages) for 1 wk. The cells were harvested for cytogenetic studies after a 2 hr treatment with colcemid (0.05 μg/ml) and processed for trypsin-Giemsa banding. The metaphases from cells at both temperatures were pseudodiploid, with numerous chromosome changes primarily affecting chromosomes 1 and 2. Other chromosomes (6, 11, and the X) were also frequently involved. A marker chromosome, LM, was present in 35% of the cells at 40.5 C. Chromosome changes have been associated with malignant transformation, making the SV40 tsA-transformed cells an interesting model to determine the relationship of modulation (temperature shift) of the transformed phenotype to chromosome changes. (12 refs)

78-4027 **Transcription, Processing and Structure of Chromatin in SV40-transformed Cell.** (Eng) Chae, C. B. (Dept. Biochemistry, Univ. North Carolina, Chapel Hill, NC, 27514); Wong, T. K.; Gadski, R. A. *Biochem Biophys Res Commun* 83(4): 1518-1524; 1978.

The transcription, processing, and structure of chromatin in simian virus 40 (SV40)-transformed 3T3 cells (SVB209) cells, which contain one copy of the SV40 genome, were studied. Nuclear RNA from SVB209 cells was hybridized with a trace amount of the separated strands of tritium-labeled SV40 DNA. When the nuclear RNA was hybridized with the E strand, the entire length of the viral DNA strand was transcribed. However, only 40% of the L strand was transcribed in the SVB209 cells. Examination of the RNA extracted from the cytoplasm showed that the E strand was derived from 55% of the SV40 DNA. Therefore, although the entire length of the E strand of SV40 DNA is transcribed, only half the length of the RNA is transported into the cytoplasm. More than 90% of the SV40 DNA in the nuclei of SVB209 cells was completely digested by DNase I. Hybridization experiments indicated that this result was not due to the generation of very short DNA fragments by DNase I. It is most likely a result of structural modification of the chromatin. The sensitivity of >90% of the SV40 DNA in the SVB209 nuclei is in good agreement with transcription of the entire length of the E strand of this DNA in the cell. It appears, however, that both strands of the SV40 DNA in the transformed cell are sensitive to DNase I. (24 refs)

78-4028 **Nucleotide Sequence of the Simian Virus 40 Small-t Gene.** (Eng) Volckaert, G. (Lab. Molecular Biology, State Univ. Ghent, Ledeganckstraat 35, B 9000 Ghent, Belgium); Van de Voorde, A.; Fiers, W. *Proc Natl Acad Sci USA* 75(5): 2160-2164; 1978.

The nucleotide sequence of simian virus 40 (SV40) DNA between map positions 0.649 and 0.533 is presented. This segment is approx half of the restriction fragment *Hin*d A, it is
located near the beginning of the early region, and it is tra
scribed counterclockwise. A potential initiating ATG codo
is located 13 nucleotides from the *Hin*d C-*Hin*d A junctio
in the strand with the same polarity as early messenger RN
From this signal on, an open reading frame is present th
would allow the synthesis of a polypeptide of 174 amino aci
until a TAA termination codon is reached at nucleotide 6
(map position 0.547). DNA sequence analysis indicated th
this polypeptide corresponds almost exactly to small (t) t
mor antigen. Correlation of the deduced amino acid sequen
with the NH_2-terminal sequences of SV40 small t and lar
T antigens suggests that both proteins are initiated at t
ATG triplet. Because the DNA region between 0.547 a
0.534 is blocked for translation in all three reading fram
by multiple termination codons, it is concluded that the lar
T antigen must be coded for by two noncontiguous DN
segments: the segment from 0.65 to approx 0.60, which bo
antigens share, and another segment starting at some poi
after position 0.534 and continuing counterclockwise until
terminates at map position 0.174. Small t antigen is methi
nine-rich and has a remarkably high number of cysteine re
dues clustered mainly in its COOH-terminal half. It is ri
in both basic and acidic residues, with the former being sligh
ly in excess. (37 refs)

78-4029 **Large and Small Tumor Antigens from Simi
Virus 40 Have Identical Amino Termini Ma
ping at 0.65 Map Units.** (Eng) Paucha, E. (Translation La
Imperial Cancer Res. Fund, Lincoln's Inn Fields, Lond
WC2A 3PX, England); Mellor, A.; Harvey, R.; Smith, A.
Hewick, R. M.; Waterfield, M. D. *Proc Natl Acad Sci U*
75(5): 2165-2169; 1978.

Large and small tumor (T) antigens of simian virus 40 (SV4
were synthesized in vitro with L-cell extracts that had be
treated to prevent amino-terminal acetylation of nascent pr
teins to determine whether both antigens share the sa
amino-terminal amino acid sequence. The partial amino-t
minal amino acid sequences of both forms of T antigen we
identical. Methionine residues were located at positions 1 a
14, a lysine residue at position 3, and leucine residues at po
tions 5, 11, 13, 16, 17, and 19. These amino acid sequen
data match perfectly the amino acid sequence predicted fro
a sequence of nucleotides in the E strand of SV40 DNA th
begins near the junction between *Hin*dII/III fragments A a
C, at about 0.65 map unit. This finding strongly suggests th
the sequence coding for the amino terminus of both protei
is located at this position. The data are consistent with
model for the synthesis of both forms of T antigen that pr
dicts that (1) small T antigen is coded for by a sequence
nucleotides from the 5′ end of the early region and (2) lar
T antigen is coded for by nucleotide sequences from two no
contiguous regions of SV40 DNA. (31 refs)

78-4030 **Contact-inhibited Revertant Cell Lines Isolat
from SV40-transformed Cells. VIII. Membra**

Protein and Glycoprotein Composition. (Eng) Vessey, A. R. (Dept. Immunology, Cleveland Clinic Foundation, Cleveland, OH, 44106); Culp, L. A. *Virology* 86(2): 556-561; 1978.

The compositions of enriched surface membrane preparations from BALB/c 3T3 simian virus 40 (SV40)-transformed 3T3 (SVT2), and concanavalin A-selected revertant variant cells were investigated by sodium dodecyl sulfate-polyacrylamide gel electrophoresis. The electrophoretic profiles of the membrane proteins from the three cell lines were similar. However, ^{14}C-leucine-labeled or Coomassie blue-stained preparations from revertant cells lacked a protein band of 110,000 mol wt (band 15) that was present in 3T3 and SVT2 membranes and that was replaced in revertant membranes by two new bands (15a and 15b) migrating on either side of band 15. Lactoperoxidase-catalyzed iodination studies indicated that the relative proportion of band 5 [presumptive LETS (large external transformation-sensitive) glycoprotein] was decreased and that of band 24 (mol wt, 65,000) was increased in 3T3 cells, compared with the other cell lines. Revertant membranes had increased proportions of sialic acid residues on several glycoproteins. The LETS glycoprotein from all three cell types was found to be sialylated. Two different compartmentalized pools of cell surface-associated LETS were identified. These results are discussed in relation to the method of selection of revertant cells and to possible changes induced in cell surface architecture by transformation and reversion. (20 refs)

78-4031 **Detection of Antigenically Active Mutant HGPRT after Mutagenesis with Simian Virus 40.** (Eng) Strauss, M. (Dept. Cell Genetics, Div. Bioregulation, Central Inst. Molecular Biology, Acad. Sciences GDR, DDR-1115 Berlin-Buch, E. Germany); Theile, M.; Eckert, R.; Geissler, E. *Mutat Res* 51(2): 297-300; 1978.

An antigenically active mutant hypoxanthine-guanosine phosphoribosyltransferase (HGPRT) was detected in Chinese hamster cells following infection with simian virus 40 (SV40). Inhibition assays with V79-4 wild-type cell extracts demonstrated that 50 μl of the tenfold diluted antibody soln were required to precipitate the max amount of HGPRT protein from 50 μg of cell-extract protein. The titration curve of the amount of antibody against the residual enzymatic activity in the supernatant soln demonstrated a region of linear dependence. In this region, the addition of 5 μl of the antibody soln led to a residual enzymatic activity of 70%, but 10 μl antibody soln caused enzymatic activity of only 36%. The amount of cross-reacting material (CRM) or the antigenicity of mutant HGPRT enzymes from virus-induced and spontaneous mutants was determined quantitatively. For each individual clone, the enzymatic activity was between 4,350 and 2,350 disintegrations/min. The CRM values for the six clones ranged from 60% for clone V5 to 100% for clone V150. Therefore, all the virus-induced and spontaneous mutants examined were CRM-positive. Most of the clones seemed to synthesize normal amounts of HGPRT enzyme protein (80%-100%). Thus, the HGPRT enzyme proteins must be caused by point mutations. (12 refs)

78-4032 **Higher Order Structure of Simian Virus 40 Chromatin. Histone H1 Is Responsible for the Condensation of Intranuclear Viral DNA-Protein Complexes.** (Eng) Muller, U. (Dept. Microbiology, Univ. Heidelberg, Im Neuenheimer Feld 230, D-69 Heidelberg, W. Germany); Zentgraf, H.; Eicken, I.; Keller, W. *Science* 201(4354): 406-415; 1978.

Viral DNA-protein complexes isolated from the nuclei of cultured cells infected with simian virus 40 (SV40) were used to study the conditions required for the formation and maintenance of the higher order chromatin structure. At moderate ionic strength, SV40 nucleoprotein complexes contain histone H1 as well as the nucleosomal histones, and they have a compact conformation made up of globular subunits with an av diameter of 190 A. At high ionic strength, histone H1 is released and the structure unfolds into chains averaging 24 nucleosomes in length. Such H1-depleted nucleoprotein complexes can be brought back to a compact state by the addition of purified histone H1 in vitro. Transcriptionally active SV40 chromatin undergoes the same structural transitions. The higher order structure of viral chromatin may be analogous to the compact state of cellular chromatin fibers observed at physiological ionic strength. It appears that the higher order organization of chromatin does not interfere with DNA replication and transcription. (57 refs)

78-4033 **Role of the Simian Virus 40 Gene *A* Product in Regulation of DNA Synthesis in Transformed Cells.** (Eng) Butel, J. S. (Dept. Virology and Epidemiology, Baylor Coll. Medicine, Houston, TX, 77030); Soule, H. R. *J Virol* 26(3): 584-594; 1978.

The kinetics of induction of DNA synthesis were determined for hamster cell lines transformed by temperature-sensitive (*ts*A) mutants of simian virus 40 (SV40). The hamster transformants were shifted to the permissive temperature (33 C) after a 48-hr serum arrest at the nonpermissive temperature (40.5 C). DNA synthesis was initiated in the *ts*A transformants by 8 hr after shiftdown and was max by 12 hr, as determined by incorporation of ^{3}H-thymidine (^{3}H-TdR). The presence or absence of fetal bovine serum at the time of temperature shift had no effect on the kinetics of initiation of DNA synthesis. Analysis of thymidine triphosphate (TTP) in *ts*A transformants revealed simi incorporation of ^{3}H-TdR into TTP at both permissive and nonpermissive temperatures. Autoradiography revealed that by 12 hr after a shift to the permissive temperature, approx 50% of the cells had labeled nuclei after a 60-min pulse with ^{3}H-TdR, indicating that most of the cells were actively synthesizing DNA. By 8-12 hr after a shiftup of confluent *ts*A transformants to the nonpermissive temperature, the number of labeled nuclei was reduced to 16%, regardless of serum concentration. These results indicate that the SV40 gene *A* product directly or indirectly regulates cellular DNA synthesis in transformed cells. (58 refs)

78-4034 **Differences in Behavior and Prognosis Between Leukemic and Lymphomatous Forms of a Transplantable Hamster Lymphocytic Neoplasm Induced by Simian Virus 40.** (Eng) Diamandopoulos, G. T. (Dept. Pathology, Harvard Medical Sch., 25 Shattuck St., Boston, MA, 02115). *Proc Natl Acad Sci USA* 75(4): 2011-2015; 1978.

A lymphocytic leukemia, induced in a Syrian golden hamster by iv injection of simian virus 40, was adapted to grow in the allogeneic host either as leukemia or as lymphoma. The leukemia was produced by transplanting sc neoplastic lymphocytes that had circulated through and/or proliferated in lymph nodes and spleen, and it was characterized by dissemination with systemic manifestations and poor prognosis. The lymphoma was produced by transplanting sc neoplastic lymphocytes that had proliferated at sc sites of cell implantation, and it was characterized by localization and favorable prognosis. The tissue environment that the neoplastic lymphocytes encountered during circulation and/or proliferation must have regulated their subsequent behavior in the intact host. Since the leukemic and lymphomatous forms of this animal model resemble very closely the analogous human lymphocytic neoplasms, the model can be used to study factors responsible for the differences in the behavior of these neoplasms and to determine how these differences may influence prognosis and response to therapy. (27 refs)

78-4035 **Altered Metabolism of Heparan Sulfate in Simian Virus 40 Transformed Cloned Mouse Cells.** (Eng) Winterbourne, D. J. (Macromolecular Biology Section, NCI, NIH, Bethesda, MD, 20014); Mora, P. T. *J Biol Chem* 253(14): 5109-5120; 1978.

Comparisons were made between glycoconjugates (GC's) from a family of closely related cell lines derived from AL/N mouse embryos: a parent clone and three daughter subclones, two of which expressed simian virus 40 (SV40) tumor (T) antigen. Papain-digested macromolecules from the parent, labeled with ^{3}H-glucosamine, and from one of the subclones, labeled with ^{14}C-glucosamine, were compared simultaneously by diethylaminoethylcellulose chromatography. Three culture compartments (the medium, the cell-surface trypsinate, and the cells) from the paired cell lines were combined at the earliest time during the harvesting of the cells. The results demonstrated a close relationship among alterations in the metabolism of heparan sulfate, the expression of SV40-specific T antigen, and the ability of the cells to grow to high densities in monolayer culture, but not in suspension in viscous medium. Apart from the altered elution of HS produced by the T-antigen-positive subclones, the salt concentration at which any given GC eluted from the ion-exchange columns was highly reproducible and similar for each cell line. This allowed preliminary identification of the GC's and assured that the GC's of the individual compartments in each experiment were not subject to unrecognized differences in the isolation procedure. The T-antigen-positive subclones had essentially the same tumorigenicity as the parent clone, which had relatively low tumorigenicity in syngeneic AL/N and nude mice. (49 refs)

78-4036 **Mapping of *H-2* Genes Associated with T Cell-mediated Cytotoxic Responses to SV40-Tumour-associated Specific Antigens.** (Eng) Pfizenmaier, K. (Wistar Inst. Anatomy and Biology, 36th St. at Spruce, Philadelphia, PA, 19104); Trinchieri, G.; Solter, D.; Knowles, B. B. *Nature* 274(5672): 691-693; 1978.

The primary cytotoxic responses to simian virus 40 (SV40) tumor-associated specific antigens (TASA) were investigated in B10 and BALB/c mice, and the genes associated with these responses were mapped. The mice were immunized with SV40, and the antigenic specificity of the cytotoxic T lymphocytes (CTL) was determined using SV40- and adenovirus 5 (Ad5)-transformed cells as targets in the ^{51}Cr-release assay. Max cytotoxic activity was obtained in both strains 7 days after in vivo immunization followed by a further 3-day in vitro culture period. CTL could be demonstrated in B10 mice when tested directly 7 days after immunization, and this response was enhanced by in vitro culture. CTL could be demonstrated in BALB/c mice only after the in vitro culture. Target cell lysis was SV40-TASA-specific and syngeneically restricted, as neither Ad5- nor allogeneic SV40-transformed cells were lysed. The findings suggest that suppressor mechanisms may account for the eclipse in immunity in mice bearing syngeneic SV40-induced tumors. Mapping experiments using lymph node cells from various strains of SV40-immunized mice showed that the cytotoxic response to SV40-TASA was associated with the *Kb, Kk, Db,* and *Dd* but not with the *Kd* and *Dk* genes of the major histocompatibility (*H-2*) complex. There may also be a possible *Ir* gene influence on the T cell response to SV40-TASA associated with *H-2Dd*. (20 refs)

78-4037 **Synthesis of the SV40 Viral Polypeptide Vp1 During Infection.** (Eng) Kasamatsu, H. (Molecular Biology Inst., Univ. California, 405 Hilgrad Ave., Los Angeles, CA, 90024); Flory, P. J. *Virology* 86(2): 344-353; 1978.

The synthesis of simian virus 40 (SV40) polypeptides in permissively infected CV-1 cells was studied by a sensitive method in which ^{125}I-labeled antibodies are used to identify and quantitate polypeptides immobilized in gels. The synthesis of Vp1 begins about 24 hr postinfection, with the majority of this polypeptide being found in the nucleus. Smaller quantities of several Vp1-related polypeptides were observed in highly purified virions. Two of these species, with apparent mol wts of about 117,000 and 100,000, were also found in infected cells. They appeared long after Vp1 synthesis had begun, at about 54 hr postinfection in the nuclei and at about 95 hr postinfection in the cytoplasm. (26 refs)

78-4038 **1 Biosynthesis, Immunological Specificity, and Intracellular Distribution of the Simian Virus 40-specific Protein Induced by the Nondefective Hybrid Ad2+ND$_1$.** (Eng) Jay, G. (Pediatric Oncology Branch, NCI, NIH, Bethesda, MD, 20014); Jay, F. T.; Friedman, R. M.; Levine, A. S. *J Virol* 26(2): 411-419; 1978.

A study was made of the synthesis, immunological specificity, and intracellular distribution of a 28,000 (28K)-mol wt protein induced by Ad2+ND$_1$, a nondefective hybrid virus containing a segment of the early region of simian virus 40 (SV40) DNA covalently inserted into the human adenovirus 2 genome. Radioimmunoprecipitation using sera from hamsters bearing SV40-specific tumors indicated that the Ad2+ND$_1$-induced 28K protein is SV40-specific. This protein was synthesized as a 30K-mol wt precursor, and it was detectable only when infected cells were pulse-labeled in the presence of a protease inhibitor. Fractionation of labeled cell extracts revealed that 80% of the 28K protein was in the plasma membrane fraction and that 20% was associated with the outer nuclear membrane. Blockage of proteolytic cleavage did not alter the topographic distribution of the 28K protein; however, the amount of the 30K precursor in the outer nuclear membrane increased fourfold while that in the plasma membrane decreased proportionately. This suggests that the 28K protein is transferred from the outer nuclear membrane to the plasma membrane after posttranslational cleavage of the 30K precursor polypeptide. The data support the proposal that the 28K protein contains the determinants for SV40 U antigen and that it is responsible for SV40 enhancement of adenovirus growth in simian cells. (28 refs)

78-4039 **Studies on the Occurrence of High Molecular Weight Adenovirus Type 2 DNA in Productively Infected Cells.** (Eng) Fanning, E. (Inst. Genetics Fachbereich Biologie, Univ. Konstanz, D-7750 Konstanz, W. Germany); Schick, J.; Doerfler, W. *Virology* 88(1): 186-190; 1978.

The conditions under which high-mol-wt adenovirus type 2 (Ad2) DNA is formed and the factors that determine its quantity and quality were studied. High-mol-wt viral DNA (> 100S and 50S-90S) occurred in Ad2-infected KB, HeLa, and HEK cells and, to a lesser extent, in WI-38, XP4, XP25, BHK21, and CHO cells. The proportion of Ad2 DNA sequences in the 50S-90S DNA varied from one cell line to another, and it declined markedly with increasing cell density. The proportion of newly synthesized DNA in the > 100S, 50S-90S, and < 20S size classes was dependent on the multiplicity of Ad2 infection. In KB cells infected with UV-inactivated Ad2, synthesis of 34S viral DNA, but not high-mol-wt DNA, was reduced or nearly abolished. The data suggest that the synthesis of high-mol-wt viral DNA does not depend on the concurrent synthesis of 34S viral DNA, but that it does require active cell growth, possibly cellular DNA replication. (20 refs)

78-4040 **Adenovirus DNA-directed Transcription of 5.5S RNA In Vitro.** (Eng) Wu, G. J. (Dept. Microbiology, Emory Univ. Sch. Medicine, Atlanta, GA, 30322). *Proc Natl Acad Sci USA* 75(5): 2175-2179; 1978.

A mammalian cell-free and membrane-free system developed from human KB cells was used to investigate the synthesis and regulation of a 5.5S RNA that is produced in adenovirus type 2-infected KB or HeLa cells. Cell-free RNA synthesis was dependent upon exogenous templates, ribonucleoside triphosphates, and the cell-free postmitochondrial supernatant of human KB cells. The synthesis of 5.5S RNA was inhibited only by high levels of α-amanitin (≥ 100 μg/ml); therefore, it was performed by RNA polymerase III. The rate of synthesis was linear for at least 2 hr, indicating reinitiation. The 5.5S RNA synthesized in vitro was similar to the corresponding in vivo RNA in size, sequence, and coding region on adenovirus type 2 DNA. (35 refs)

78-4041 **Synthesis of Transfer Ribonucleic Acid in KB Cells Infected with Adenovirus Type 2.** (Eng) Sehulster, L. M. (Dept. Pathology, CMDNJ-Rutgers Medical Sch., Piscataway, NJ); Varricchio, F.; Raska, K. *J Gen Virol* 40(part 1): 183-194; 1978.

New techniques for separating low-mol-wt (LMW) RNA allowed examination of the synthesis of LMW RNA and changes in transfer RNA (tRNA) synthesis during infection of KB cells with adenovirus type 2. Cells were labeled postinfection (PI), with ^{3}H-uridine or ^{32}P. An increasing amount of virus-coded LMW RNA was detected from 8 hr PI onward. The rate of synthesis of tRNA was unchanged 0-16 hr PI, but it decreased thereafter. From 24 to 48 hr PI, the specific activity of tRNA was about 60% of the control value. The specific activity of cellular 5S RNA increased from 12 hr PI. Two-dimensional gel electrophoresis resolved the tRNA into 42-47 spots, so that changes in tRNA synthesis in individual spots could be seen. From 8 to 12 hr PI, the relative rate of incorporation into RNA increased in seven spots and decreased in eight. At 12-16 hr PI, incorporation into RNA increased in six spots, especially in spot 9 (sevenfold). Simultaneously, incorporation in six spots decreased. At 24-34 hr PI, RNA synthesis increased in eight spots and decreased in eight. Incorporation into RNA in two spots was virtually shut off. The material that migrated in spot 9 contained tRNA. It is hypothesized that increased amounts of a specific tRNA species are required for optimal synthesis of virus DNA in infected cells and that the marked increased RNA synthesis in spot 9 reflects this requirement. Assuming that reproducible changes of incorporation into specific RNA spots reflect changed rates of synthesis of specific individual tRNA species (and not modifications of preexisting tRNA after virus infection), the results show that changes, transient or permanent, in the utilization of certain tRNA's resulting from adenovirus infection can be reflected in the tRNA synthesis rates. However, some of the changes may be due to alterations in the relative mobility of tRNA's, reflecting changes in their primary structure. (38 refs)

78-4042 **Infectivity and Oncogenicity of DNA from Simian Adenovirus SA7 (C8) and Infectivity of DNA from Human Adenovirus Type 6.** (Rus) Vikhnovich, E. M. (D. I. Ivanovskii Inst. Virology, Moscow, USSR); Dreizin, R. S.; Zolotarskaia, E. E.; Chaplygina, N. M.; Ponomareva, T. I.; Gol'dberg, E. Z. *Vopr Virusol* (2): 176-179; 1978.

The infectivity of the DNA from human adenovirus type 6 and the infectivity and oncogenicity of the DNA from simian adenovirus SA7 (C8) was studied in newborn hamsters. Inoculation of the hamsters with isolated DNA from SA7 (5-10 μg, sc) induced tumors in 1/2, 1/9, and 2/9 animals (in three different experiments). The induced tumors contained tumor (T) antigen, and sera derived from the tumor-bearers contained complement-binding antibodies against T antigen. Isolation of the virus from a green monkey kidney cell culture infected with the DNA of SA7 and from a KV cell culture and a human embryo kidney cell culture infected with the DNA of adenovirus type 6 indicated the infectivity of the isolated viral DNA. (9 refs)

78-4043 **Localization of Simian Adenovirus 7 (SA 7) Transcription and Replication in Lytic Infection. An Ultracytochemical and Autoradiographical Study.** (Eng) Moyne, G. (Institut de Recherches Scientifiques sur le Cancer, B.P. no. 8, F-94800 Villejuif, France); Pichard, E.; Bernhard, W. *J Gen Virol* 40(part 1): 77-92; 1978.

High-resolution cytochemistry and autoradiography were used to determine the precise localization of DNA transcription and replication in the nucleus of cells (kidney cells of *Cercopithecus aethiops*) infected with simian adenovirus 7. The majority of studies were made with cells taken 24 hr postinfection, when most cells contained virus particles. The morphology of the nucleus was essentially similar to that of cells infected by other adenoviruses, except that the nucleolus was distinct from the main inclusion body. The nucleolus incorporated uridine much more actively than both the inclusion body and cellular chromatin. Conventional staining distinguished dense and clear fibrillar inclusions in addition to virus particles. Use of a DNA-specific stain allowed the direct visualization of newly formed DNA-containing structures before the appearance of other nuclear alterations. Up to four degrees of DNA packing in the infected cell nucleus were demonstrated: chromatin, types A and B fibrils, and the nucleoids of the virus particles. The A and B fibrils were equated with the clear and dense fibrillar inclusions, respectively. The B fibrils probably represented virus DNA produced in excess in adenovirus-infected cells, the A fibrils the actively transcribing and replicating form of DNA. These findings were confirmed by ribonucleoprotein (RNP) preferential staining and enzymic extractions. The use of serial sections showed that the DNA and RNP staining techniques were complementary. Correlation of these findings with high-resolution autoradiography revealed that virus DNA replication and transcription are carried out in the clear fibrillar inclusions. The functional role of host cell chromatin and of the nucleolus is discussed. (33 refs)

78-4044 **Immunohistochemistry of Local Immunoglobulin Production in Nasopharyngeal Carcinoma.** (Eng) Ho, H. C. (Medical Health Dept., Queen Elizabeth Hosp., Kowloon, Hong Kong); Kwan, H. C.; Ng, M. H. *Br J Cancer* 37(4): 514-519; 1978.

Biopsy specimens from 36 nasopharyngeal carcinoma (NPC) patients were studied histochemically for antibody production by the immunoperoxidase method. Electron micrographs of stained biopsy sections revealed an accumulation of plasma cells, particularly the IgA type, in the connective tissue surrounding nests of tumor cells. The extent of accumulation varied in the different biopsy specimens, which included 35 poorly differentiated, nonkeratinizing squamous or undifferentiated carcinomas and 1 moderately differentiated squamous carcinoma. IgA+ plasma cells were also observed in the submucosal stroma of a choanal polyp, but they were found infrequently in the uninvolved mucosa of a patient with oropharyngeal carcinoma. There was no correlation between the occurrence of IgA+ plasma cells and titers of serum IgA antibodies to Epstein-Barr virus (EBV) capsid antigen. The results suggest that the nasopharynx is the site of local antibody production in response to antigenic stimulation by NPC cells. The local antibody response might also involve the production of antibodies to EBV antigens. (16 refs)

78-4045 **Transforming Activity of Epstein-Barr Virus Obtained by Superinfection of Raji Cells.** (Eng) Yajima, Y. (Dept. Microbiology, Rush-Presbyterian-St. Lukes's Medical Center, Chicago, IL, 60612); Marczynska, B.; Nonoyama, M. *Proc Natl Acad Sci USA* 75(4): 2008-2010; 1978.

Human cord blood lymphocytes were transformed by Epstein-Barr virus (EBV; SI Raji virus) obtained by superinfection of Raji cells with EBV recovered from P3HR1 cells (HR1 virus). A human lymphoblastoid cell line, HLB, established by this transformation contained 22 EVB genomes per cell and EBV-associated nuclear antigen; a few cells contained early or viral capsid antigen complexes. Chromosome analysis revealed that HLB cells were diploid, with normal female karyotypes. Replication of EBV DNA and inhibition of host cell DNA synthesis were observed in HLB cells after superinfection with HR1 virus. Two possibilities are considered for the origin of SI Raji virus. (1) SI Raji virus DNA is the replicational result of parental HR1 virus DNA. HR1 virus DNA is modified or partially deleted during replication of virus DNA, resulting in production of defective virus with transforming activity, (2) SI Raji virus DNA is derived from resident EBV DNA in Raji cells. The regulatory mechanism controlling the expression of EBV genomes in Raji cells is destroyed by HR1 infection, leading to the replication of latent EBV DNA. (11 refs)

78-4046 **Relationship Between Epstein-Barr Virus (EBV)-Production and the Loss of the EBV Receptor/Complement Receptor Complex in a Series of Sublines Derived from the Same Original Burkitt's Lymphoma.** (Eng) Klein, G. (Dept. Tumor Biology, Karolinska Institutet, S-10401, Stockholm 60, Sweden); Yefenov, E.; Falk, K.; Westman, A. *Int J Cancer* 21(5): 552-560; 1978.

Virus production, Epstein-Barr virus (EBV, P3HR-1 substrain) superinfectability, iododeoxyuridine (IUdR) inducibility, and expression of EBV and complement (C3) receptors were assessed in (1) two independently maintained Jijoye Burkitt's lymphoma lines; (2) the P3HR-1 clone that releases a nontransforming, cytopathic, and growth-inhibiting viral mutant; and (3) nonproducer P3HR-1 sublines. Both Jijoye lines were superinfectable and inducible, and they carried EBV and C3 receptors. The virus-producing P3HR-1 cells and their nonproducer sublines lacked EBV and C3 receptors and they could not be superinfected, but they were inducible with IUdR. Of two long-passaged nonproducer sublines that reexpressed EBV and C3 receptors, the one with the higher expression also manifested P3HR-1 viral superinfectability. These findings support the hypothesis that the EBV/C3 receptor negativity of P3HR-1 and its sublines is due to negative selection by the growth inhibitory, cytopathic P3HR-1 virus variant. The closely linked disappearance and reappearance of the EBV and C3 receptors suggests that they are identical or closely linked membrane constituents. (30 refs)

78-4047 **Recovery of Transforming EBV from Non-producer Cells after Superinfection with Non-transforming P3HR-1 EBV.** (Eng) Fresen, K. O. (Institut Virologie, Zentrum Hygiene, Universitat Freiburg, Hermann-Herder-Strasse 11, 7800 Freiburg, W. Germany); Cho, M. S.; zur Hausen, H. *Int J Cancer* 22(4): 378-383; 1978.

The viral progeny released after superinfection of nonproducer lymphoblastoid cell lines with Epstein-Barr virus (EBV) were characterized and compared with the input virus. Treatment of Raji (a Burkitt's lymphoma-derived cell line) or NC37 (derived from the peripheral blood of an EBV-seroreactive donor) cells with iododeoxyuridine (IUdR) or the tumor promoter 12-O-tetradecanoylphorbol-13-acetate resulted in induction of early antigen (EA) only. After superinfection by nontransforming P3HR-1 EBV, however, 5.5% of Raji cells and 6.0% of NC37 cells showed viral capsid antigen (VCA) synthesis. Viral particles were seen in the supernatants of these cells 5 days after superinfection. Infection of cord blood lymphocytes with supernatants from P3HR-1 EBV-superinfected Raji or NC37 cells led to transformation and resulted in the establishment of EB nuclear antigen-positive permanently growing lymphoblastoid cell lines. Infection of P3HR-1 EBV-converted BJA-B cells (an EBV-genome-negative human B-lymphoma cell line) led to EA and VCA induction and the release of nontransforming viral particles. When permanently growing lymphoblastoid cell lines established after infection of human cord blood lymphocytes with supernatants of P3HR-1-superinfected Raji or NC37 cell lines or with transforming B95/8-EBV were compared, only one cell line, NC37-RI, spontaneously expressed EA (8.5% of the cells) produced VCA (6%), and had transforming properties. These results suggest that viral genomes persisting within Raji and NC37 cells are defective and become complemented by the superinfecting P3HR-1 virus. (30 refs)

78-4048 **Epstein-Barr Virus in Somatic Cell Hybrids Between Mouse Cells and Human Nasopharyngeal Carcinoma Cells.** (Eng) Steplewski, Z. (Wistar Inst. Anatomy and Biology, 36th St. at Spruce, Philadelphia, PA, 19104); Koprowski, H.; Andersson-Anvret, M.; Klein, G. *J Cell Physiol* 97(1): 1-8; 1978.

Somatic cell hybrids were produced between human nasopharyngeal carcinoma (NPC) cells and mouse cells to determine whether the expression of Epstein-Barr nuclear antigen (EBNA) in the hybrid cells is related to the retention of a specific human chromosome(s) derived from NPC patients. NPC cells were taken from biopsy specimens or from NPC tumors that had been maintained in nude mice. Three mouse cell lines were used: two deficient in thymidine kinase and one deficient in hypoxanthine phosphoribosyltransferase. Fusion of NPC and mouse cells resulted in 13 independent hybrid lines, 10 of which contained cells with EBNA-positive nuclei. In some clones derived from these lines, 90% of the EBNA-positive cells were maintained for > 6 mo; in others, the number of EBNA-positive cells decreased to 10%-20% during this time. Although human chromosomes 12 and 21 (or parts of them) appeared to be preferentially retained in the EBNA-positive hybrid cells, subcloning indicated that neither of these chromosomes segregated with EBNA. Thus, it was impossible to correlate the presence of EB virus (EBV) DNA and the expression of EBNA with a specific human chromosome(s). It is suggested that the production of EBNA is associated with a human chromosome fragment carrying EBV DNA sequences that cannot be detected by karyotype analysis or isozyme assays. (29 refs)

78-4049 **Studies on the Association of the Epstein-Barr Virus Genome and Human Chromosomes.** (Eng) Glaser, R. (Dept. Medical Microbiology, Ohio State Univ. Coll. Medicine, Columbus, OH, 43210); Nonoyama, M.; Hampar, B.; Croce, C. M. *J Cell Physiol* 96(1): 319-326; 1978.

Cloned and subcloned mouse fibroblast/Burkitt's lymphoma hybrid cells(Cl1D/HR-1) were used in attempts to identify a specific human chromosome(s) that is associated with the Epstein-Barr virus (EBV) genome. Ten clones of CL1D/Hr-1 cells were assayed for the spontaneous expression of early antigen (EA) and virus capsid antigen (VCA) by indirect immunofluorescence, but no EA- or VCA-positive cells were found. Attempts to induce EA and VCA with iododeoxyuridine were unsuccessful. Clone M44 and four of its subclones were assayed for EBV DNA and the presence of human chromosomes. Subclone 5 [EB nuclear antigen (EBNA)-negative] and subclone 4 (2%-3% EBNA-positive) had no detectable levels of EBV DNA. Clone M44 and subclones 2 and 24 ($\geq$ 90% EBNA-positive) contained 0.4-0.6 EBV genome equivalent/cell. Examination of Giemsa-banded metaphase chromosomes and isozyme analysis were used to determine the presence of human chromosomes. Five intact human chromosomes (7, 1, 12, 15, 17) were found in at least 10% of the M44 cells, but in none of the four subclone cells. A human marker chromosome derived from human chromsome 14 was present in all four subclones, and all four expressed human nucleoside phosphorylase activity. It is concluded that the EBV genome is not associated with any specific human chromosome in the cell line studied. (19 refs)

78-4050 **Reversible Inhibition by Phosphonoacetic Acid of Human B Lymphocyte Transformation by Epstein-Barr Virus.** (Eng) Thorley-Lawson, D. A. (Sidney Farber Cancer Inst, Harvard Medical Sch., Boston, MA, 02115); Strominger, J. L. *Virology* 86(2): 423-431; 1978.

Adult peripheral blood B lymphocytes, purified by immunoabsorbent chromatography, were used to study the kinetics of DNA synthesis due to Epstein-Barr virus (EBV) infection. The kinetics showed two phases: an early phase, lasting 3-4 days, the rate and absolute level of which depended on the multiplicity of infection, and a later phase, representing normal exponential growth, the level but not rate of which depended on multiplicity of infection. The time of induction of DNA synthesis (24 hr) agreed well with published times for the appearance of EBV nuclear antigen (EBNA). Absorption and penetration of the cells by EBV required 1-2 hr. The induction of DNA synthesis proceeded normally during the first phase in the presence of phosphonoacetic acid (PAA: 200 μg/ml). Thereafter, DNA synthesis remained at a plateau. Blast-transformed EBNA-positive cells could be isolated from these cultures. Removal of PAA at any time up to 28 days postinfection resulted in resumed proliferation and outgrowth in the presence of PAA, these cells expressed four phenotypic properties of transformation by EBV: (1) induction of DNA synthesis, (2) EBNA expression, (3) blast transformation, and (4) immortalization (survival for at least 28 days). However, they did not proliferate. It is, therefore, proposed that EBV infection in the presence of PAA may be termed abortive transformation. (21 refs)

78-4051 **Transformation of Lymphocytes by Herpesviruses: A Molecular Model for Transformation of Viral Genomes by the Host Restriction Enzymes and Recombination of Transforming Genes with the Chromosomal DNA.** (Eng) Becker, Y. (Lab. Molecular Virology, Hebrew Univ.-Hadassah Medical Sch., Jerusalem, Israel). *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 226-227; 1978.

A model for the transformation of lymphocytes by herpesviruses is presented. A figure eight-shaped herpesvirus DNA molecule is cleaved at the X junction, resulting in a circular molecule that is incapable of selfreplication. However, if cleavage results in the liberation of fragments containing the S component of the viral DNA, these fragments can be incorporated into the host DNA. The host cell is induced to produce a restriction enzyme that cleaves the circular viral DNA, and transcription and replication occur. (9 refs)

78-4052 **Delay of Tumor Growth in Hamsters Treated with Lynestrenol and Effect of *Staphylococcus aureus* Cowan A.** (Eng) Wybran, J. (Dept. Immunology, Saint-Pierre Univ. Hosp., 322 rue Haute, 1000 Brussels, Belgium); Thiry, L. *J Natl Cancer Inst* 61(1): 173-176; 1978.

The influence of lynestrenol, a synthetic progesteronelike substance, and of *Staphylococcus aureus* Cowan A on the growth of tumors induced by malignant cells transformed by herpes simplex virus type 1 (HSV-1) was studied in Syrian golden hamsters. The hamsters received ip injections of 1, 0.1, or 0.01 mg/kg lynestrenol and/or 0.1 ml of a 10% suspension of killed *S. aureus* from the day of birth. Some hamsters were inoculated sc 1 day after the start of therapy with 2 x 10^5 viable transformed cells and some were inoculated with 2 x 10^6 viable cells when they were 6 wk old. In most instances, a dose of 1 mg/kg lynestrenol delayed tumor growth for 1 wk at day 18. *S. aureus* alone did not delay tumor appearance. Survivals were best among animals receiving lynestrenol + *S. aureus*. Survivors showed an increased resistance to challenge with infected cells. Hamsters previously given injections of 10^7 killed transformed cells and then challenged with 2 x 10^5 viable cells showed a facilitation of tumor growth. This facilitation was inhibited by lynestrenol alone or in combination with *S. aureus*. It is suggested that these effects are related to an immunopotentiating property of lynestrenol. (11 refs)

78-4053 **The Transfer and Stable Integration of the HSV Thymidine Kinase Gene into Mouse Cells.** (Eng) Pellicer, A. (Inst. Cancer Res., Columbia Univ., 701 W. 168th St., New York, NY, 10032); Wigler, M.; Axel, R.; Silverstein, S. *Cell* 14(1): 133-141; 1978.

Treatment of mutant cells (Ltk-) deficient in thymidine kinase with Bam I reduction endonuclease-cleaved herpes simplex virus type 1 (HSV-1) DNA results in the appearance of numerous surviving colonies with a stable tk+ phenotype. Through a series of electrophoretic fractionations association with transfection assays, a 3.4 kilobar fragment was isolated that contained the thymidine kinase gene (*tk*) and that transfected *tk* activity to Ltk- cells. The distribution of *tk* sequences in the DNA of several transformed clones following stable gene transfer was examined in a series of complementary experiments involving reassociation kinetics in soln and annealings with *tk* DNA to restriction-cleaved cellular DNA following electrophoresis and transfer to filters. In all clones examined, the *tk* gene was present in all cells at a frequency of one copy per chromosomal complement. The *tk* gene was integrated stably in the DNA of the transformants, but integration was not site-specific as it occurred at different loci in the DNA of all transformants. The existence of a single active *tk* gene in tk+ transformants will facilitate analysis of the sequence organization of tk- mutant cells and provide a useful model system for studies of the transfer of cellular genes. (16 refs)

78-4054 **Oncogenic Properties of Herpesviruses.** (Eng) Munk, K. (Institut fur Virusforschung, Deutsches Krebsforschungszentrum, Im Neuenheimer Feld 280, 6900 Heidelberg, W. Germany); Flugel, R. M.; Braun, R.; Darai, G. *In: Characterization and Treatment of Human Tumours. Proceedings of the Seventh International Symposium on the Biological Characterization of Human Tumours held in Budapest, April 13-15, 1977.* Davis, W.; Harrap, K. R., eds. (Amsterdam: Excerpta Medica): Advances in Tumour Prevention, Detection and Characterization. Vol. 4, 332 pp.; 22-29; 1978.

The oncogenicity of the herpes simplex virus (HSV) strains HSV-1 Thea, HSV-2 Muller, and HSV-2-HG-52 and of cytomegalovirus (CMV) were investigated. When rat embryo fibroblasts (REF) were infected with HSV, transformed cells had a two- to threefold higher plating efficiency than normal cells. New cell colonies showed two different morphologies, epitheliallike or spindlelike. Clones were isolated from these colonies and established in tissue culture. The modal chromosome number of the transformed cells was >42, the modal number of primary rat cells. The spindlelike transformed cells grew in soft agar, but the epitheliallike cells did not. In newborn Sprague-Dawley rats, the transformed cells with the spindlelike morphology were highly tumorigenic, producing spindle cell sarcomas that grew rapidly and metastasized to the lung. Immunofluorescence revealed the presence of HSV antigens in the cytoplasm of the spindlelike cells but not in that of the epitheliallike cells. The spindlelike cells were resistant to superinfection with HSV types 1 and 2, and the superinfectability of the epitheliallike cells was reduced considerably, compared with REF cells. Further studies with human CMV demonstrated infection of hamster embryo fibroblasts, and persistent infection of human embryo lung fibroblasts (nonpermissive and permissive cell systems, respectively). Human and tree shrew cells were also transformed by CMV; both cell types exhibited CMV-specific immunofluorescence and were resistant to superinfection with CMV. (42 refs)

78-4055 **Latent Herpes Cervicitis and Mixed Cervical Carcinoma.** (Eng) Lauchlan, S. C. (Dept. Pathology, Women and Infants Hosp. Rhode Island, 50 Maude St., Providence, RI, 02908). *Am J Obstet Gynecol* 131(1): 109-110; 1978.

A 25-yr-old woman with an adenosquamous carcinoma of the cervix was found to have herpesviruslike intranuclear inclusions in several paracervical neurons. Although positive virologic identification of the inclusions was not made, their appearance was consistent with that of herpesvirus hominis, probably type 2. (2 refs)

78-4056 **Conditions Required for Induction of Murine p30 by Herpes Simplex Virus.** (Eng) Isom, H. (Dept. Microbiology, Milton S. Hershey Medical Center, Pennsylvania State Univ. Coll. Medicine, Hershey, PA, 17033); Colberg, A.; Reed, C.; Rapp, F. *Int J Cancer* 22(1): 22-27; 1978.

An attempt was made to confirm previous findings that infection of NIH Swiss mouse cells (N cellA cell10) with herpes simplex virus type 2 (HSV-2), strain 333, induces the expression of murine leukemia virus (MuLV) p30 antigen, as measured by indirect immunofluorescence (IIF). An attempt was also made to quantitate the IIF results by competition radioimmunoassay (RIA) and to determine the conditions of virus infection required for p30 induction. Uninfected N clA cl10 cells contain 1.2-2.5 nanograms of p30/mg protein; this amount of antigen could be detected by RIA, but not by IIF. Induction of p30 by HSV-2 was multiplicity-dependent, and it was optimal 8 hr postinfection when cells at 50%-70% confluence were infected at a multiplicity of infection (MOI) of 5-8 plaque-forming units/cell. At an MOI of 2.5, 70%-80% of the cells expressed HSV antigens, but none of the cells expressed p30; at an MOI of 5.0, 70%-80% of the cells expressed HSV antigens, and 55% of the cells expressed p30. Inhibition of virus DNA synthesis alone or both virus and cell DNA synthesis had no effect on p30 induction. Attempts to quantitate the IIF results by RIA were not successful: the HSV-2-induced increase in p30 was not detectable by RIA. It is likely that HSV-2 infection causes the p30 to become sufficiently labile so that the protein is degraded or altered during the preparation of competing antigen and it cannot be measured by RIA. (12 refs)

78-4057 The Phosphorylation of Histones in Herpes Virus Infected Vervet-Monkey Kidney Cells (CV-1). (Eng) Letnansky, K. (Inst. Cancer Res., Univ. Vienna, Vienna, Austria); Dostal, V.; Reiss-Gutfreund, R. J. *Oesterr Z Onkol* 4(2-3): 39-41; 1977.

The phosphorylation of histones in African green monkey kidney cells (CV-1) infected with herpes simplex virus type 2 (HSV-2, strain MS, 5 plaque-forming units/cell) was investigated. The incorporation of phosphate into histone fractions was diminished during the early periods after virus infection. This result was consistent with the observation that DNA replication is repressed during this period. However, 14-15 hr postinfection, high amounts of phosphate (twice control values) were incorporated into histones of the F1 group, fraction F2a1, and, particularly, fraction F2a2. It is not known whether these histones were of cellular or viral origin. At the same time, large amounts of DNA were produced; as demonstrated by separation experiments in cesium chloride gradients, this DNA was primarily of viral origin. It is suggested that the stimulated phosphorylation of these histone fractions is a prerequisite for the enhanced synthesis of DNA and, possibly, of RNA. (13 refs)

78-4058 Alkaline DNase Activity in Cells Infected with a Temperature-sensitive Mutant of Herpes Simplex Virus Type 2. (Eng) Francke, B. (Tumor Virology Lab., Salk Inst. Biological Studies, San Diego, CA, 92112); Moss, H.; Timbury, M. C.; Hay, J. *J Virol* 26(2): 209-213; 1978.

Experiments were conducted to determine whether the temperature-sensitive mutant *ts*13 of herpes simplex virus type 2 (HSV-2) represents the structural gene for viral alkaline nuclease. Baby hamster kidney cells (BHK-21) infected with *ts*13 at a nonpermissive temperature lacked alkaline nuclease activity, which was induced by the mutant at a permissive temperature and by wild-type virus at either temperature. For *ts*13, enzyme activity could be induced by a temperature shift to permissive conditions, but not in the presence of cycloheximide. After a shift from permissive to nonpermissive conditions in the presence of cycloheximide, the activity was stable in wild-type, but not in mutant-infected, cells. After extensive purification, the wild-type nuclease was four times more heat stable in the presence of substrate than was the mutant enzyme. These results indicate that two temperature-sensitive functions can be defined in *ts*13, one related to the virus particle and likely to be a structural polypeptide and the other the viral nuclease activity. 78-4059 **Antitumor Immunity after Surgical Removal of 3-Methylcholanthrene-induced Murine Tumors: Correlation Between Resistance and Delayed Hypersensitivity Reaction.** (Eng) Abe, S. (Faculty Pharmaceutical Sciences, Univ. Tokyo, Hongo 7-3-1, Bunkyo-ku, Tokyo 113, Japan); Yamazaki, M.; Mizuno, D. *Gann* 69(3): 323-329; 1978.

The relationship between tumor resistance and the antitumor delayed hypersensitivity reaction (ATDHR) after tumor resection was studied with the use of the syngeneic 3-methylcholanthrene-induced murine tumor, MCA-DDD. MCA-DDD was inoculated sc into the tail of DDD mice and, 4 wk later, the tumor-bearing tail was resected. The tumor resistance of the mice was then determined from the diameters of the tumor that developed 14 days after sc challenge of the mice with tumor cells in the flank. The mice showed a specific resistance to the tumor until 30 days after tumor resection. In parallel with tests on tumor resistance, the ATDHR of the mice after tumor resection was examined by the footpad test. The tumor antigen fraction was a cell-free extract of sonicated MCA-DDD tumor cells. The ATDHR of the mice appeared soon after tumor resection, reached a max on day 7, and then decreased slowly until day 29. Mice that acquired tumor resistance showed a rapid increase in ATDHR after challenge with fresh tumor cells. The ATDHR was high on day 4 after challenge, and its level correlated well with the tumor resistance of the mice. (14 refs)

78-4060 **Modulation of Virus-induced Tumor Antigens (MLr) on Murine Leukemia Cells.** (Eng) Feltkamp, C. A. (Div. Cell Biology, Antoni van Leeuwenhoekhuis, Netherlands Cancer Inst., Sarphatistraat 108, Amsterdam, Netherlands); Wilschut, I. J.; Van Blitterswijk, W. J.; Hilgers, J.; Sonnenberg, A. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 345-348; 1978.

The antibody-induced modulation of tumor antigens was studied in ascitic murine leukemia cells (GRSL), which possess mammary tumor virus (MTV)-induced cell surface antigens. Incubation of GRSL cells with anti-MTV serum at 37 C resulted in the loss of MTV antigens, as measured by the complement-dependent cytotoxicity assay. Within 15 min, the percentage of dead cells was significantly lower than that in control cultures. This early phase of modulation was paralleled by the patch formation of immune complexes. Max modulation (after a 120-min incubation) was accompanied by the shedding of part of the patches from the cell surface. The loss of antigenicity was specific for MTV cell-surface antigens, and it was not due to endocytosis or capping of immune complexes. (3 refs)

78-4061 **Involvement of the Immune System in the Spontaneous Regression of Friend Virus Induced Erythroleukemia.** (Eng) Hines, D. L. (Michigan Cancer Foundation, Detroit, MI, 48201); Dietz, M.; Marcelletti, J.; Rich, M. A.; Furmanski, P. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 233; 1978.

Studies of the role of the immune system in the spontaneous regression of erythroleukemia induced by a variant of Friend virus, RFV, suggest that the immune response to RFV-specific antigens is a major component of regression and that it is involved in maintaining the regressed state. Redevelopment of leukemia, which occurs in 50%-70% of regressed mice, may be due to loss of an effective immune response with time. RFV or RFV-leukemic cells may be antigenically different from nonregressing strains of Friend virus. (no refs)

78-4062 **Epstein-Barr Virus Infections in the X-Linked Recessive Lymphoproliferative Syndrome.** (Eng) Purtilo, D. T. (Dept. Pathology, Univ. Massachusetts Medical Sch., 55 Lake Ave., North, Worcester, MA, 01505); Bhawan, J.; Hutt, L. M.; DeNicola, L.; Szymanski, I.; Yang, J. P.; Boto, W.; Maier, R.; Thorley-Lawson, D. *Lancet* 1(8068): 798-801; 1978.

The hypothesis that immunodeficiency to Epstein-Barr virus (EBV) can lead to variable phenotypic expressions of the X-linked recessive lymphoproliferative syndrome was investigated in three brothers with the syndrome. All three had the same defective lymphoproliferative-control locus on the X chromosome but showed different phenotypic expression: brother A (16-yr-old) had hypogammaglobulinemia (HGG), fatal infectious mononucleosis (IM), and immunoblastic sarcoma without EBV antibodies; brother B (15-yr-old) had HGG and subclinical EBV infection with EBV antibodies; after treatment, he has been symptom-free for 8 mo since EBV infection; brother C (18-yr-old) had histiocytic lymphoma; he survives recurrence-free 6 yr postresection. HGG and measles pneumonitis had preceded EBV infection in brothers A and B. The diverse phenotypic expressions probably resulted from the varied immune response to EBV. However, the difference could also be explained in part by environmental factors: C was separated from his two brothers since the age of 3. A and B had shared the same bedroom and, probably, the same microorganisms. Xg blood-grouping of the RBC of A and B revealed that A was (a+), but B was (a-). Both T-cell activity and the capacity to form EBV antibodies were defective in A. The apparent recombination of the X chromosome of B, however, equipped him with immune defenses that prevented IM from appearing. T-cell proliferation in a lymph node of B vs T-cell depletion with B-cell replacement in the lymphoid tissues of A supports this view. In conclusion, EBV can produce diverse lymphoproliferative disorders and can be potentially oncogenic in immunodeficient patients. (24 refs)

78-4063 **The Molecular Nature of the Gross Cell-Surface Antigen (GCSA).** (Eng) Snyder, H. W. (Memorial Sloan-Kettering Cancer Center, New York, NY); Stockert, E.; Fleissner, E. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 353-354; 1977.

Gross virus-induced leukemia E(male)G2 cells were examined for the presence of surface molecules carrying Gross cell-surface antigen (GCSA). The leukemia cells expressed glycosylated murine leukemia virus core (gag) polyproteins on their surface. These polyproteins bore the antigenic determinants of GCSA. (6 refs)

78-4064 **Cellular Immunity to Solubilized Tumor Antigens of a Methylcholanthrene-induced Sarcoma with a Migration Inhibition Assay.** (Eng) Padarathsingh, M. L. (Dept. Immunology, Biomedical Res. Div., Litton Bionetics, Inc., Kensington, MD, 20795); Dean, J. H.; McCoy, J. L.; Lewis, D. D.; Northing, J. W.; Natori, T.; Law, L. W. *J Immunol* 120(6): 1981-1985; 1978.

BALB/c mice immunized with Nonidet P-40 (NP-40) crude solubilized (CS) extracts of a syngeneic methylcholanthrene-induced BALB/c sarcoma (Meth A) were challenged with viable Meth A cells to determine the ability of the solubilized preparations to induce transplantation rejection. Animals resisting such challenge were then used in agarose microdroplet macrophage migration inhibition (MMI) and tumor cell neutralization (Winn) assays to evaluate the antigenic specificity of these CS extracts. Spleen cells from animals that rejected Meth A after immunization with the NP-40-solubilized preparations effectively neutralized the tumor-producing capacity of Meth A tumor cells, as determined in Winn assays. The MMI assays were quite sensitive; migration inhibition of peritoneal exudate (PE) cells from immunized mice was detected with extract concentrations as low as picogram quantities. Meth A expressed no antigenic cross-reactivity with similarly prepared extracts of an unrelated simian virus 40-induced sarcoma (mKSA) or with a mineral oil-induced plasmacytoma (ADJ-PC5) of BALB/c mice. Inhibition of PE cell migration was mediated by culture supernatants (presumably migration inhibition factor) generated from a mixture of immune spleen cells and mitomycin C-treated Meth A cells, as assayed in an indirect MMI test. Although extracts from strongly antigenic murine tumor systems may permit strong MMI reactivity, this observation may not necessarily hold for human systems. (30 refs)

78-4065 **Suppressed Murine Mammary Tumor Virus (MuMTV) Expression in RIII Female Mice Treated Neonatally with Goat Antiserum to MuMTV.** (Eng) Frensdorff, A. (Dept. Microbiology, Faculty Life Science, Dr. George S. Wise Centre Life Sciences, Tel Aviv Univ., Tel Aviv, Israel); Wald, A. *J Natl Cancer Inst* 61(2): 437-439; 1978.

Newborn inbred R3/Imr mice were passively immunized with goat antiserum to murine mammary tumor virus (α MuMTV) according to two schedules, and the influence of α-MuMTV on MuMTV expression was studied. Schedule A mice received 10 im injections of whole goat No. 2 antiserum to MuMTV (α-MuMTV$_2$) or normal goat serum (NGS) in increasing dosage to a total of 3.75 ml serum/mouse over 21 days. Schedule B mice received 10 im injections of the globulin fraction of α-MuMTV$_2$ or NGS, each in amounts equivalent to 500 μl of original serum to a total of 5.0 ml serum equivalent/mouse over 21 days. At 1 mo of age, females were mated with untreated R$_3$ males, and milk samples were collected from mothers on days 7-10 postpartum upon the 3rd, 6th and 9th pregnancies. The milk was tested for MuMTV antigen by double diffusion in agar gels and by radial immunodiffusion. Milk from mice given NGS and from untreated mice contained MuMTV antigens at the third lactation, but a considerable part of third lactation milk from all immunized mice was negative. In addition, 4/12 mice born at third parity to mothers on Schedule A and 6/12 born to mothers on Schedule B were negative with respect to MuMTV antigens. At the fourth parity, all mice on Schedule A (12) were positive for MuMTV antigens, but 4/8 on Schedule B were still negative. The 14 females that remained antigen-negative at the sixth lactation bore no tumors, even though 10 were $>$9.5 mo old, whereas spontaneous mammary tumors had arisen in 100% of corresponding controls, between 4.5 and 9 mo of age. Early administration of goat antiserum to MuMTV to newborn R3 mice apparently leads to delay and even suppression of MuMTV expression. (12 refs)

78-4066 **Suppression of Leukemogenesis in Hairless Mice by Anti-Type C Viral Immune Gamma Globulins.** (Eng) Pottathil, R. (Jackson Lab., Bar Harbor, ME, 04609); Meier, H.; Huebner, R. J. *Naturwissenschaften* 65(8): 443-444; 1978.

The suppression of leukemogenesis by passive neonatal immunization against ecotropic murine leukemia virus (MuLV) was investigated in the hairless mouse, HRS/J--*hr/hr*. Haired and hairless littermates were given a total of 0.45 ml anti-radiation leukemia virus goat IgG. This preparation had a neutralizing antibody titer of 1:800 to 1:1,600. Each mouse received, sc, 0.05 ml on days 0, 4, and 7; 0.1 ml on day 10; and 0.2 ml on day 14. MuLV titers were assayed at 1, 3, and 6 mo, and the mice were observed until moribund, at which time they were killed and evaluated histopathologically. Immunized haired and hairless mice showed a significant reduction in MuLV titers compared with control mice. IgG-treated hairless mice had a very low rate of leukemia occurrence (2/14 at 16 mo), compared with untreated mutants (8/13 at 16 mo). There was no appreciable difference in leukemia incidence between treated and untreated normal (haired) mice. The reduction in leukemia incidence of treated hairless mice in conjunction with lowered ecotropic virus titers tends to verify the existence of a close relationship between high endogenous ecotropic MuLV expression and leukemia susceptibility. These results confirm the applicability of antibody therapy to virus-associated malignancies. (17 refs)

78-4067 **Paraproteinemia in Normal Family Members of Eight Cases with Primary Intestinal Lymphomas in Iraq.** (Eng) Alsabti, E. A. (Philharmonic Residence, Flat N4, Liverpool L8 7SD, England). *Oncology* 35(2): 68-72; 1978.

The immunoglobulin patterns of six men and two women (8-28 yr old) with primary intestinal lymphoma were investigated. Immunoelectrophoresis of the serum proteins from all patients showed the IgA heavy chain disease pattern. The clinical, laboratory, radiological, and histopathological data for these patients were suggestive of the malabsorption syndrome. Immunoelectrophoresis of serum from the 129 normal family members of the 8 patients revealed the IgA heavy chain pattern in 23 persons from four of these families. This finding suggests that a hereditary factor may be involved in the production of alpha-chain diseases and that these 23 persons should be closely monitored for the development of intestinal lymphoma. (30 refs)

78-4068 **A Possible Role of Prostaglandins in the Inhibition of Natural and Antibody-dependent Cell-mediated Cytotoxicity Against Tumor Cells.** (Eng) Droller, M. J. (Dept. Immunology, Wenner-Gren Inst., Univ. Stockholm, Stockholm, Sweden); Schneider, M. U.; Perlmann, P. *Cell Immunol* 39(1): 165-177; 1978.

The effects of prostaglandins E_1 and E_2 on natural and antibody-dependent lymphocyte cytotoxicity against the T_{24} and HCV_{29} tumor lines were examined to determine whether prostaglandin production by the tumor cells could alter the cellular immune response. The T_{24} line was derived from a transitional cell tumor of the bladder; line HCV_{29}, obtained from normal bladder epithelium of a patient successfully treated for bladder carcinoma by radiotherapy, had become transformed upon passaging in tissue culture. The target cell lines were labeled with ^{51}Cr and incubated at 37 C for various times with lymphocytes prepared from the venous blood of normal donors. Antiserum to T_{24} and varying concentrations of prostaglandin E_1 or E_2 were added to the samples prior to incubation. In some experiments, lymphocytes or labeled target cells were preincubated with prostaglandins and then washed prior to their addition to the assay tubes. Cytotoxicity was determined by measuring the release of ^{51}Cr from the target cells after incubation. Both prostaglandins inhibited natural and antibody-dependent lymphocyte cytotoxicity against the target cells. The effect on lymphocytes appeared to be direct, and it was amplified by the presence of theophylline in the medium. Inhibition could be effected early in lymphocyte/target cell interaction, and only a short exposure of lymphocytes to prostaglandins was required for the effect to be manifested. The production of prostaglandins by tumor cells may constitute a mechanism by which the tumor cells subvert the effect of a cellular immune response directed against them. (26 refs)

78-4069 **Differentiation Linked Expression of p28,33 (Ia-like) Structures on Human Leukaemic Cells.** (Eng) Janossy, G. (Membrane Immunology Lab., Imperial Cancer Res. Fund, London, England); Goldstone, A. H.; Capellaro, D.; Greaves, M. F.; Kulenkampff, J.; Pippard, M.; Welsh, K. *Br J Haematol* 37(3): 391-402; 1977.

A differentiation-linked expression of Ia-like (B-cell-associated) structures was detected by heterologous antisera against p28,33 antigen on human leukemia cells. A double fluorochrome immunofluorescence test was used to distinguish Ia+ (p28,33+) leukemia cells from B lymphocytes, and leukemia cells with varying intensities of anti-p28,33 staining were separated. p28,33 was very strongly expressed on undifferentiated blast cells from Philadelphia chromosome (Ph^1)-positive lymphoid blast crisis and non-T, non-B acute lymphoid leukemia. In Ph^1-positive myeloid blast crisis and in acute myeloid leukemia, the p28,33 antigen was only moderately strongly expressed on myeloblasts and virtually absent on promyelocytes. The p28,33 antigen was also absent on the relatively more mature cells during the chronic phase of chronic myeloid leukemia. Nonleukemic samples (bone marrow samples from fetuses and from patients with a severe megaloblastic anemia or myeloid hyperplasia) also contained p28,33-positive immature blast cells. These observations suggest that Ia-like antigens on leukemia cells reflect the origin of the leukemias from hemopoietic stem cells, which are themselves Ia-positive. It is also suggested that Ia-like membrane structures are stem cell markers that may play an important role in the immunological responses of B cells and in the regulation of early hemopoietic cell differentiation. (29 refs)

78-4070 **Cell Surface Immunoglobulins of Bovine Leukemic Cells.** (Eng) Trainin, Z. (Dept. Immunology, Kimron Veterinary Inst., Bet Dagan, Israel); Ungar-Waron, H.; Meirom, R.; Glueckmann, A.; Gavish, M.; Katzav, S.; Haimovich, J. *In: Advances in Comparative Leukemia Research 1977. Proceedings of of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 253-254; 1978.

The cell surface immunoglobulins of peripheral blood lymphocytes (PBL) from normal and leukemic cattle were compared. IgM was present on PBL from 2/4 leukemic cows: 60%-80% of the PBL exhibited IgM, compared with 20% of normal cow PBL. Electrophoresis indicated that the μ-chain from the IgM of leukemic PBL migrated slower than that from the IgM of normal PBL. These μ-chains had mol wts of 95,000 and 85,000, respectively. Since lymphoid tumor cells do not exhibit membrane IgM, it is suggested that two clones of lymphoid cells are involved in bovine leukemia. (6 refs)

78-4071 **Kinetic Studies of Surface Markers on the Pathological Cells of Hairy Cell Leukaemia (HCL) and Chronic Lymphocytic Leukaemia (CLL).** (Eng) Burns, G. F. (Dept. Haematological Medicine, Univ. Cambridge, Cambridge, England); Cawley, J. C.; Barker, C. R.; Nash, A. A.; Rees, J. K.; Worman, G. P.; Hayhoe, F. G. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 251-252; 1978.

The expression of surface markers was studied on pathological B cells from six patients with hairy cell leukemia (HCL) and four patients with chronic lymphocytic leukemia (CLL). HCL and CLL cells each possessed distinct receptors for IgG and IgM. The IgM receptor was spontaneously shed and reexpressed in a cyclical fashion, with a peak-to-peak reexpression time of 6 hr in HCl and 12 hr in CLL. Surface membrane immunoglobulin markers were thought to be removed from the cell membrane as soon as they were expressed. (4 refs)

78-4072 **Pre-B-Cell Leukemia. A New Phenotype of Childhood Lymphoblastic Leukemia.** (Eng) Vogler, L. B. (224 Tumor Inst., Univ. Alabama in Birmingham, Birmingham, AL, 35294); Crist, W. M.; Bockman, D. E.; Pearl, E. R.; Lawton, A. R.; Cooper, M. D. *N Engl J Med* 298(16): 872-878; 1978.

Leukemic cells from children with acute lymphoblastic leukemia were examined for lymphocyte markers characteristically acquired at different stages of development. Large lymphoid cells containing small amounts of cytoplasmic IgM (cIgM) but undetectable surface immunoglobulin (sIg) have been recognized recently as precursors of B lymphocytes. In 4/22 consecutive patients (2.5-15 yr old), leukemic cells had the cIgM+.sIg-phenotype of pre-B cells. The cells of these patients shared common acute lymphoblastic leukemia antigens and B-cell alloantigens, but differed in expression of several developmental features characteristic of the B-cell lines. Pre-B-cell leukemias were readily responsive to chemotherapy. It is concluded that a distinct subpopulation of previously unclassified leukemias reflects oncogenic transformation at the earliest recognizable stage in differentiation along the B-cell axis. (38 refs)

78-4073 **Genetically Determined Immunodeficiency Diseases (GDID) and Malignancy: Report from the Immunodeficiency-Cancer Registry.** (Eng) Spector, B. D. (Dept. Lab. Medicine and Pathology, Univ. Minnesota, Minneapolis, MN, 55455); Perry, G. S.; Kersey, J. H. *Clin Immunol Immunopathol* 11(1): 12-29; 1978.

Cases reported to the Immunodeficiency-Cancer Registry (ICR) were updated, resulting in new data related to the association between immunodeficiency and malignancy. There were 267 patients with both genetically determined immunodeficiency diseases (GDID) and malignancies in the ICR. The 267 subjects fell into 13 different GDID categories. The predominant tumor histology was non-Hodgkin's lymphoma and lymphoid leukemia (158/267). There were an additional 42 mesenchymal tumors that arose in cells other than the lymphocytic-reticuloendothelial series, including Hodgkin's disease (22), and myelogenous leukemia (9). Of the 65 epithelial tumors, 11 affected the nervous system only. In the remaining 54 cases, the major sites were stomach (21 cancers), lung (6), genitals (6), and skin (4). Among the 11 cases in which the results of surface marker studies of malignant blast cells were reported to ICR, 7 had phenotypes that were B-like in origin, 2 were T-like, and 2 were non-B, non-T. The data revealed the following malignancy patterns: (1) if a child with a GDID develops a malignancy, it will most likely be a non-Hodgkin's lymphoma, whereas adults will develop non-Hodgkin's lymphomas and carcinomas in about equal proportions; (2) in most GDID's, the general malignancy type is lymphoreticular; and (3) the most common single histologic type of non-Hodgkin's lymphoma is histiocytic lymphoma. Although the case material in the registry is valid, the methods of reporting the cases may have resulted in certain biases, such as the over- or underreporting of tumors occurring in certain GDID's. (64 refs)

78-4074 **Human Malignant Lymphomas In Vitro.** (Eng) Sundstrom, C. (Wallenberg Lab., P.O. Box 562, S-751 22 Uppsala, Sweden); Nilsson, K. *Acta Pathol Microbiol Scand (A)* 86(2): 173-184; 1978.

A series of 55 biopsies from different types of malignant lymphomas were characterized in short-term culture experiments and during prolonged growth in vitro. Most of the lymphocytic (LC) lymphomas and half of the histiocytic (HC) lymphomas expressed surface immunoglobulin, either in monoclonal or polyclonal form, indicating B-lymphocyte derivation. No lysozyme production was noted in either type of lymphoma, giving further support to the notion that HC lymphomas are not truly HC. Production of β_2-microglobulin was higher in HC than in LC lymphoma and Hodgkin's disease, but it did not differ significantly from the production observed in nonneoplastic lymph node disorders. Incorporation of ^{3}H-thymidine varied greatly within each category of lymphoma; the highest mean labeling index was noted in HC lymphoma, possibly reflecting the generally more malignant course in these cases. Epstein-Barr virus-associated nuclear antigen was observed in one case of Hodgkin's disease. Attempts to establish permanent tumor cell lines were successful only from two explants of LC lymphoma and one pleural effusion from a HC lymphoma. The two cell lines derived from LC lymphomas both exhibited B-lymphocyte characteristics. The HC lymphoma line lacked lymphocyte markers, produced lysozyme, and was found to be rich in cytoplasmic esterases. These features are consistent with a true HC derivation of this line. Lymphoblastoid cell lines representing nonneoplastic EBV-carrying lymphocytes contaminating the biopsies were derived from 19 biopsies, 10 of which were from cases of Hodgkin's disease. The tumor lines were all EBV-genome-negative. (83 refs)

78-4075 **The Influence of Embryonal Bursectomy on Benzpyrene-induced Sarcoma of the Chicken.** (Eng) Niedorf, H. R. (Inst. Pathology, Univ. Munster, Westring 17, D-4400 Munster, W. Germany); Lusznat, A.; Hultsch, E.; Grundmann, E. *Z Krebsforsch* 91(3): 323-334; 1978.

The effect of embryonal bursectomy on the incidence, growth, and metastatic spread of benzo(a)pyrene (BP)-induced sarcomas was studied in specifically virus-free chicks. There were two groups of 160 chicks: Group B was bursectomized on day 3 of embryonic life by immersion of the eggs into testosterone propionate. Group C (controls) was not bursectomized. All chicks were inoculated with BP (10 mg im) 2 and 6 wk posthatching. At 18 wk posthatching, 78 Group B and 129 Group C chicks had survived, and tumors could be palpated in 4 of the former, 6 of the latter. From wk 20 onward, however, Group B chicks showed a lower tumor incidence than Group C. At 24 wk, tumor incidence was 32.1% and 49.6%, respectively ($p \leq 0.012$). Light and electron microscopy identified the tumors as malignant polymorphocellular rhabdomyosarcomas. At 27 wks, tumor incidence in Group B chicks (58.9%) was closer to that of Group C (65.1%), which shows that bursectomy prolonged tumor latency. Metastases were found in 10/46 Group B tumor-bearers and in 35/84 Group C tumor-bearers. They were most common in the liver (7 Group B chicks, 21 Group C) and lungs (5 Group B, 19 Group C). Many animals had metastases in more than one site. These findings are an illustration of the disturbed equilibrium between T- and B-cell responses. (50 refs)

78-4076 **Immunosuppressive Activity of Antibody Directed Against Endogenous C-type Virus Interferes with Early Events of the Immune Response.** (Eng) Schumann, G. (Res. Dept., Pharmaceuticals Div., CIBA-GEIGY Limited, R-1056.4.13, CH-4002 Basel, Switzerland); Moroni, C. *J Immunol* 120(6): 1913-1916; 1978.

The physiologic role of endogenous viruses in the immune system was examined by testing the effect of antiserum directed against BALB/c endogenous xenotropic C-type virus on the humoral immune response of mice. Both in vivo and in vitro, this serum suppressed the response to sheep RBC, an effect that could be absorbed out by purified BALB/c xenotropic C-type virus or Friend leukemia virus, but not by Rous sarcoma virus. The serum produced its max effect when administered with or prior to the antigen, but not 24 hr later. This suggests that the antibody acts on an early event in the immune response. The critical viral antigen was expressed before the spleen cells were experimentally stimulated by the antigen. The same immunosuppressive effect was observed in a variety of mouse strains, including high-leukemia-incidence AKR mice and virus-free 129/J mice; this indicated that the immunosuppressive effect is independent of endogenous virus. The binding of antibody to viral antigen on the cell membrane may lead to steric hindrance of immunologic receptor structures, or the viral antigen itself may play a receptorlike role. If endogenous viruses are actively involved in the triggering of lymphocytes to form a clone of dividing cells, it may be possible to find a link between this system and leukemias in which C-type viruses are known to play a role. (19 refs)

78-4077 **Incidence of Spontaneous Ileocecal Immunocytomas in Hybrids of LOU/C Rats and Rat Strains with Low Spontaneous Tumor Incidence: Brief Communication.** (Eng) Becker, A. (Experimental Immunology Unit, Univ. Louvain, Box 3056, 30 Clos Chapelle-aux-Champs, 1200 Brussels, Belgium); Bazin, H. *J Natl Cancer Inst* 60(6): 1505-1508; 1978.

The incidence of spontaneous ileocecal immunocytomas in LOU/C, LOU/M, AxC, and Okamoto (OKA) rats and the F_1 hybrids of LOU/C x (1) AxC, (2) AUG, and (3) OKA rats was determined. Male and female tumor incidence in the respective strains was 31.6% and 16.1%, 0.7% and 2.1%, 4.2% and 1.9%, 0% and 0%, 18.5% and 14.1%, 16.7% and 7.8%, and 0% and 0%. In LOU/C rats, the susceptibility to immunocytomas was under genetic control: these rats contained a dominant locus or loci of susceptibility that could induce immunocytoma in inbred AUG and inbred AxC rats. However, inbred OKA rats had at least one dominant locus of resistance that did not exist in the other strains. The class distribution of monoclonal immunoglobulins originating in male and female rats and in the various hybrids did not differ significantly. Most tumors that originated appeared to develop in the ileocecal lymph node. A total of 710/720 spontaneous tumors that were transplanted into histocompatible rats grew during the first passage. Almost all tumors that were successfully transplanted continued to be transplantable in histocompatible hosts. (23 refs)

78-4078 **An Athymic Nude Mutation in the Rat.** (Eng) Festing, M. F. (MRC Lab. Animals Centre, Woodmansterne Road, Carshalton, Surrey, England); May, D.; Connors, T. A.; Lovell, D.; Sparrow, S. *Nature* 274(5669): 365-366; 1978.

The morphology and biological behavior of homozygous nude rats that originated from an athymic hairless mutation in 1953 are reported. The thymus is replaced by brown fat tissue, although there is a small and highly abnormal thymus rudiment. Nude rats grow to only about 60% to 80% of the size of their heterozygous littermates, and the preweaning mortality of nude rats is higher than that of their heterozygous littermates. Homozygous nude rats of both sexes are fertile. Nude rats are able to accept xenografts of skin and tumors. The output of thoracic duct lymphocytes 24 hr after cannulation is reduced to 15% to 25% of control values, and T-cell function is depressed or absent. Nude rats are killed within 10-13 days by an infection of the larvae of the tapeworm *Taenia crassiceps* which does not normally kill immunologically competent rats. Small-scale attempts to grow tumors in these rats have had mixed success. A plasma cell tumor specific to BALB/c mice and a human colon tumor grew for a short time in two rats and then regressed. In contrast, the TLX5 lymphoma grew rapidly in 4/6 nude rats, although it largely remained localized. The nude rat is in many ways similar to the nude mouse and is of potential usefulness in biomedical research. (5 refs)

78-4079 **Immunity to Transplantable Carcinogen-induced Fibrosarcomas in B2/B2 Chickens.** (Eng) Palladino, M. A. (New York Univ., New York, NY, 10003). *Diss Abstr Int B* 39(4): 1700; 1978. (no refs)

78-4080 **Effect of Adult Thymectomy on Tumour Immunity in Mice.** (Eng) Takei, F. (Dept. Microbiology, Univ. British Columbia, Vancouver, British Columbia, Canada V6T 1W5); Levy, J. G.; Kilburn, D. G. *Br J Cancer* 37(5): 723-731; 1978.

The effect of adult thymectomy (ATx) on (1) the growth of the P815 mastocytoma in DBA/2J mice, (2) the ability of mice to generate cytotoxic cells specific for P815, and (3) the ability of tumor-bearing animals to generate suppressor cells specific for this tumor was studied. Spleen cells from adult mice that had been Tx 8wk previously demonstrated a severely impaired primary cytotoxic response to P815 tumor cells, whereas their cytotoxic responses to allogeneic cells (C57BL/6) and to non-H-2 antigens (BALB/c) and their ability to form a primary antibody response to sheep RBC were unimpaired. Suppressor T cells, specific for P815 cells, appeared after 4-8 days in the thymuses of animals inoculated with P815 cells. No differences in tumor growth between ATx animals and sham-operated controls were observed, and the Tx tumor-bearing animals and untreated controls had equal levels of specific suppressor cells in their lymph nodes. Severely thymocyte-deprived mice that had been Tx, irradiated, and reconstituted with either marrow or spleen cells 8 wk before tumor implantation succumbed more rapidly to metastatic tumor than did all control animals. The data suggest that tumor immunity and temporary tumor containment, at least with this tumor line, depend on the presence of an intact immune system. (20 refs)

78-4081 **Glucan-induced Enhancement in Host Resistance to Experimental Tumors.** (Eng) Di Luzio, N. R. (Dept. Physiology, Tulane Univ. Sch. Medicine, New Orleans, LA, 70112); Hoffman, E. O.; Cook, J. A.; Browder, W.; Mansell, P. W. *In: Control of Neoplasia by Modulation of the Immune System.* Chirigos, M. A., ed.; Raven Press, New York 1977. 2: 475-499; 1977.

The influence of the macrophage stimulant, glucan, and/or glucan-activated macrophages on the growth and dissemination of acute myelogenous tumor cells was studied in Long Evans rats, as was the effect of glucan on the growth of the mouse melanoma and adenocarcinoma tumor model. Iv glucan inhibited tumor growth and promoted survival when given to rats before or after tumor cell inoculation. Sc administration of glucan at a nontumor site had little effect on the primary tumor but reduced metastases. Glucan also reversed tumor growth and metastases in rats when the primary tumor was 2% to 3% of the body wt and when infiltration of the liver, lung, and spleen had occurred. Primary tumor growth was significantly reduced when tumor cells were transplanted sc with glucan-activated peritoneal macrophages in ratios of 10:1, 2:1, and 1:1. The most pronounced inhibition of liver, lung, and spleen metastasis occurred when the tumor: macrophage ratios were 2:1 or 1:1. Facilitation of tumor growth was never observed in glucan-treated animals. Glucan, a potent nonspecific immunostimulant, has distinct advantages over the currently employed bacterial agents and should be of significant value in evaluating various concepts of immunotherapy. Activated macrophages appear to be key cells in the regulation of the internal environment against malignant cell populations. (80 refs)

78-4082 **Effect of Chemical Carcinogen Treatment on the Immunogenicity of Mouse Mammary Tumors Arising from Hyperplastic Alveolar Nodule Outgrowth Lines.** (Eng) Ruppert, B. (Dept. Cell Biology, Baylor Coll. Medicine, Texas Medical Center, Houston, TX, 77030); Wei, W.; Medina, D.; Heppner, G. H. *J Natl Cancer Inst* 61(4): 1165-1169; 1978.

The effects of chemical carcinogen treatment of precursor hyperplastic alveolar nodules (HAN) on the immunogenicity of subsequent mammary tumors were examined in female BALB/cCrgl mice. Mice were treated before or after the appearance of precursor HAN with 3-methylcholanthrene or dimethylbenzanthracene (DMBA), each 0.5 mg. The results of in vitro immunogenicity assays were compared with those of in vivo transplantation resistance tests. This comparison demonstrated that the in vitro assays predicted qualitatively and quantitatively the results from the in vivo test. With both tests, immunogenicity was frequent with tumors derived from chemically induced HAN and infrequent with those from hormonally induced HAN. The specificity of the immunogenic reactivity appeared to be unique to tumors arising from the same nodule line and did not extend to other mammary tumors (in vivo) or to a DMBA-induced rhabdomyosarcoma (in vitro). In addition, the data suggested that the immunogenicity of a tumor depends on events occurring during the development of precursor HAN rather than during the development of subsequent mammary tumors. (18 refs)

78-4083 **Solubilization and Partial Characterization of a Tumor-associated Transplantation Antigen of the Guinea Pig L_2C Leukemia.** (Eng) Hu, C. P. (Lab. Immunology, Natl. Inst. Allergy and Infectious Diseases, NIH, Bethesda, MD, 20014); Konen, T. G.; Hoes, C.; Green, I. *J Immunol* 120(5): 1521-1525; 1978.

Different methods to solubilize a tumor-associated transplantation antigen (TATA) from guinea pig L_2C leukemia cells were evaluated. These methods were papain digestion, detergent (Triton X-100 or NP-40) solubilization, and 3M KCl extraction of L_2C cells. The latter method yielded the most immunogenic TATA of L_2C cells. Immunization of normal strain 2 guinea pigs with this extract in complete Freund's adjuvant gave complete protection against a subsequent challenge with tumor cells. Immunization with papain-digested material did not lead to protection; detergent-solubilized antigen gave only partial protection. Further fractionation of the KCl extract of L_2C cells by Sephadex G-200 chromatography suggested that the immunogenic activity was present in the fraction containing materials with estimated mol wts of $<20{,}000$ daltons. (33 refs)

78-4084 **Immune Responses to Weakly Immunogenic Virally Induced Tumors. II. Suppressive Effects of the In Vivo Carried Tumor YAC.** (Eng) Devens, B. (Lautenberg Center General and Tumor Immunology, Hebrew Univ. Hadassash Medical Sch., Jersualem, Israel); Galili, N.; Deutsch, O.; Naor, D.; Klein, E. *Eur J Immunol* 8(8): 573-578; 1978.

The failure of the in vivo tumor line YAC (a Moloney Virus-induced tumor in A mice) to stimulate immunologic memory in A or C57BL/6 mice, in contrast to the in vitro subline YAC-1, was investigated. A and C57BL/6 mice were primed with the syngeneic or allogeneic tumors YAC, YAC-1, or RBL5, a Rauscher virus-induced in vitro tumor subline in C57BL/6 mice that cross-reacts serologically with YAC and YAC-1. Two wk later, their spleen cells were cultivated alone or in the presence of a syngeneic or allogeneic sensitizer. Spleen cells from unprimed animals were sensitized with the same tumors, and their responses were compared with those of the primed spleen cells. The antitumor cytotoxic response (CTR) of the cultures was tested after 6 days by ^{51}Cr-release assay. Spleen cells from A and C57BL/6 mice immunized with YAC-1 or RBL5 generated significant syngeneic cytotoxicities after cultivation in vitro. Unprimed spleen cells from these mice did not produce CTR's to their syngeneic tumors. YAC, unlike the in vitro sublines, could not stimulate a priming effect. Spleen cells from YAC-injected A mice suppressed the in vitro syngeneic CTR of primed spleen cells from YAC-1-injected mice. Spleen cells from YAC-injected C57BL/6 mice suppressed the CTR of spleen cells from RBL5-primed C57BL/6 mice. Supressor cells from YAC-primed mice can thus abrogate the CTR of differentiated memory cells from YAC-1- or RBL5-primed mice. The possible explanation of this effect is that the suppressor cells recognized idiotypic markers of their receptors on the suppressed memory cells. (10 refs)

PATHOGENESIS

78-4085 **Familial Occurrence of Chronic Lymphatic Leukemia: HLA-Antigen and Cytogenetic Studies.** (Ger) Fazekas, T. (I. Medizinische Klinik der Universitat Szeged, P. B. 469, H-6701 Szeged, Hungary); Bach, K.; Toth, S.; Bodor, F. *Wien Med Wochenschr* 128(9): 262-264; 1978.

The finding of chronic lymphatic leukemia (CLL) in a sister (born 1904) and two brothers (born 1902 and 1907) and, subsequently, in the son of the older brother is reported. Eight other sisters are unaffected (2 died in infancy of unknown causes). One of these was studied at age 55 yr, but there were no abnormal hematological findings. Three other children of the three original patients were also studied, but no relevant findings resulted. The sister died 9 yr after diagnosis of CLL. One of the brothers has been treated only for symptoms and the other with Leukeran and prednisolone. Both are doing well since diagnosis in 1972. Antigen typing of the older brother indicated human-leukocyte antigen (HLA)-A, W_{25}, B_{27}, BW_{35}. The affected son of this brother had HLA-A_1, B_5, BW_{35}. The other brother had HLA-A_1,B_5, BW_{35}. Analysis of 50 metaphases of the brother showed that both have the karyotype 46,XY. Literature on the familial incidence of leukemia is reviewed briefly. (69 refs)

78-4086 **Familial Erythroleukaemia: A Cytogenetic and Haematological Study.** (Eng) Davidson, R. J. (Haematology Unit, Dept. Pathology, Univ. Aberdeen, Foresterhill, Aberdeen AB9 2ZD, Scotland); Walker, W.; Watt, J. L.; Page, B. M. *Scand J Haematol* 20(4): 351-359; 1978.

Clinical and hematological findings in a brother and sister (aged 42 and 39 yr, respectively) with a familial myeloproliferative disorder (erythroleukemia) are presented. Their father is presumed to have died from a similar disease. The two siblings showed similar but not identical chromosomal abnormalities that were detected initially in the marrow and later in the peripheral blood. Serial studies revealed the emergence of an increasingly diverse pattern of chromosomal changes concomitant with the progression of the disease. The changes included missing B-group chromosomes, C-group additions, 47, XY and 48, XY clones in the brother, and 47, XX and 48, XX clones in the sister. Cytogenetic abnormalities were also found in 5/15 asymptomatic relatives. (23 refs.)

78-4087 **Pure RBC Aplasia Associated with Chronic Granulocytic Leukemia.** (Eng) Kitahara, M. (Div. Hematology-Oncology, Dept. Medicine, Univ. Utah Coll. Medicine, Salt Lake City, UT). *JAMA* 240(4): 376; 1978.

The rare association of pure RBC aplasia and chronic granulocytic leukemia (CGL) is reported. Philadelphia chromosome (Ph^1)-positive CGL was diagnosed in a 54-yr-old woman who presented with splenomegaly, anemia, and leukocytosis. Bone marrow examination showed myeloid hyperplasia, with a myeloid to erythroid (M:E) ratio of 6:1. Therapy with busulfan (BS: 4 mg/day for 5 wk) and allopurinol (300 mg/day) was started. Three mo later, the patient was severely anemic, with a hematocrit value of 15%. Bone marrow examination showed myeloid hyperplasia and adequate megakaryocytes, but an M:E ratio of 100:1. Bone-marrow culture was Ph^1-positive. The presence of plasma erythroblast antibodies could not be demonstrated, and the aplasia could not be reversed by immunosuppressive therapy. From the onset of aplasia to her death 3.5 yr later due to terminal transformation of CGL, the patient received $>$ 200 units of packed RBC. The administration of BS to CGL patients reduces the number of WBC but generally does not inhibit RBC production. The active granulopoiesis and megakaryopoiesis during the RBC plasia stage suggest that the stem cell compartment was fully capable of producing WBC and platelets. Therefore, a causative role for BS seems unlikely. In addition, the protracted courses of this patient provide evidence that pure RBC aplasia dose not necessarily herald the onset of blast transformation in CGL patients. (3 refs)

78-4088 **Peripheral Microthrombotic Purpura Associated with Acute Promyelocytic Leukemia in Pregnancy. A Light and Electron Microscopic Study.** (Eng) Beller, F. K. (Universitats-Frauenklinik, Westring 11, D-4400 Munster i. Westf., W. Germany); Wagner, H.; Buchner, T. *Klin Wochenschr* 56(12): 593-599; 1978.

A case of promyelocytic leukemia in a pregnant 37-yr-old woman with four children is described. The patient was hospitalized in the 28th week of pregnancy, the fetus having died 2 days previously. Peripheral microthromboses were present on the nose, fingers, and lower extremities. The patient was heparinized, which resulted in an increase in the plasma fibrinogen level, a reduction in fibrogen breakdown products, an increase in prothrombin time, and a significant paling and decrease in size of the microthrombotic lesions. Heparin treatment was stopped, labor was induced, and heparin was restarted for 3 days after delivery. The patient developed generalized cramps, became comatose, and died 9 days after delivery. Autopsy confirmed a diagnosis of acute promyelocytic leukemia with a generalized hemorrhagic diathesis and massive cerebral ventricular hemorrhage. The exacerbation of disseminated intravascular coagulation is explained by a hypercoagulable state in pregnancy in association with the as yet unknown etiology of "promyelocytic fibrinopathic leukemia." (24 refs)

78-4089 **Specificity of Acquired Clonal Chromosome Abnormalities in New Zealand Black Mice.** (Eng) Fialkow, P. J. (Div. Clinical Genetics, Dept. Obstetrics and Gynecology, Univ. Texas Health Science Center, Dallas, TX); Bryant, J. I.; Friedman, J. M. *Int J Cancer* 21(4): 505-510; 1978.

Chromosomally abnormal cells in the spleens of spontaneous lymphoreticular malignancies of New Zealand Black (NZB) mice were subjected to detailed cytogenetic analyses. Increased reticulum cell proliferation was noted upon histopathological examination of the spleens from all 10 mice studied. The numbers of extra chromosomes in the abnormal cells ranged from 2 to 13 beyond the normal diploid complement of 40. A clonal origin of the hyperdiploid cells was suggested by the fact that in each mouse the chromosome numbers in these cells clustered about a single node. This origin was confirmed by karyotypic analysis and by the occurrence of distinctive marker chromosomes. The karyotypic changes were highly nonrandom, usually involving chromosomes 15 (10/10 mice), 2 (8/10 mice), 16 or 17 (9/10 mice), and the sex chromosomes (6/10 mice). These results demonstrate the presence of an important, but as yet undefined, relationship in mice between abnormal lymphoreticular proliferation and polysomy for the 15th chromosome. They also suggest an important relationship between chromosomal alterations and tumorigenesis in NZB mice. (15 refs)

78-4090 **Hodgkin's Disease--A 'B' Neoplasm?** (Eng) Staples, W. G. (Dept. Pathology, Wellington Clinical Sch., Wellington, New Zealand); Visser, A. E. *S Afr Med J* 54(5): 186-188; 1978.

Lymph node tissue from two patients with Hodgkin's disease was studied by light microscopy using the immunoperoxidase technique with a panel of monospecific antisera. The epithelioid cells were strongly positive for muramidase, thus confirming their histiocytic nature. The Reed-Sternberg cells and mononuclear Hodgkin's cells were negative for muramidase, but showed variable positivity for gamma heavy chains and lambda and kappa light chains. The positivity with mu and alpha chains was very weak and often absent. The available evidence is conflicting and it is not yet possible to state whether Hodgkin's disease is a T- or a B-cell neoplasm. (18 refs)

78-4091 **Cultural, Morphological, Cell Membrane, Enzymatic, and Neoplastic Properties of Cell Lines Derived from a Hodgkin's Disease Lymph Node.** (Eng) Roberts, A. N. (Dept. Microbiology, Univ. Tennessee Center Health Sciences, Memphis, TN, 38163); Smith, K. L.; Dowell, B. L.; Hubbard, A. K. *Cancer Res* 38(9): 3033-3043; 1978.

A neoplastic cell line (designated HuT_{11}) was established in continuous culture from an involved lymph node of a patient with Stage IIA Hodgkin's disease (mixed cellularity type). The line is morphologically heterogeneous, consisting of mononucleate lymphoidlike cells, polygonal epithelioid cells, and mono-, bi-, and multinucleate giant cells. Four clones initiated from isolated binucleate giant cells were also established as continuous cell lines. The cloned lines are morphologically distinct and more homogeneous, although typical giant cells have consistently appeared throughout long-term culture. The HuT_{11} lines grew as monolayers in McCoy's Medium 5A supplemented with 10% fetal calf serum, with generation times of 12-14 hr and high saturation densities. Early and later passages of HuT_{11} cells were aneuploid, and all cell lines were successfully heterotransplanted in the hamster cheek pouch. Repeated indirect immunofluorescence (IF) examinations showed that each line is negative for Epstein-Barr virus nuclear antigen. Indirect IF tests in which monospecific immunoglobulins were used revealed positive membrane reactions for the γ(heavy) chain and κ(light) chain of human IgG in approx 20% of viable cells in each line; however, direct IF with anti-human IgG $F(ab')_2$ reagent failed to confirm these reactions. Rosette tests for B- and T-lymphocyte and macrophage membrane receptors were negative. All cell lines were strongly phagocytic for latex particles and neutral red dye. Cytochemical stains of the monolayers revealed abundant esterase, fluoride-resistant nonspecific esterase, acid phosphatase, and leucine aminopeptidase activities, but lysozyme assays were negative. Although some properties of the HuT_{11} lines have suggested a macrophage derivation, an undifferentiated lymphoid cell origin of the Hodgkin's neoplastic cell remains a possibility. (69 refs)

78-4092 **B-Cell Nature Malignant Lymphoma Probably Caused by EB-Virus Infection.** (Eng) Emura, I. (Dept. Pathology, Niigata Univ. Sch. Medicine, Niigata, Japan); Ohnishi, Y.; Oboshi, S. *Virchows Arch Pathol Anat Histol* 378(4): 321-328; 1978.

Herpes virus-type particles were found in the tumor tissue of a 58-yr-old man with a sarcomatous type of malignant reticulosis that appeared to be B-cell lymphoma. Electron microscopy of tumor cells removed from the pericardial fluid revealed herpes-type virus particles in the nuclei. Epstein-Barr virus (EBV)-associated nuclear antigen and virus capsid antigen were found in the tumor cells, the pericardial fluid, and in cultivated cells. Serological studies revealed high anti-toxoplasma antibody levels in the pericardial fluid and in the serum. Both EBV and toxoplasma infections are assumed to have played an important role in the pathogenesis of this tumor. (8 refs)

78-4093 **Malignant Lymphoma and Multicentric Colonic Carcinomas as a Complication of Long-standing Ulcerative Colitis.** (Ger) Otto, H. F. (Pathologisches Institut der Universitat, Martinistrasse 52, 2000 Hamburg 20, W. Germany); Gebbers, J. O.; Matthaes, P.; Muller-Wieland, K. *Inn Med* 5(5): 189-195; 1978.

A 40-yr-old man with a 14-yr history of ulcerative colitis underwent total proctocolectomy for a rectal adenocarcinoma. Histologic examination of the operative specimen revealed two Dukes A carcinomas of the rectum and splenic flexure, multiple adenomatous and villous precancerous lesions, and one lymphoblastic-type malignant lymphoma of the upper sigmoid colon. A review of the literature revealed 18 cases of malignant non-Hodgkin's lymphoma and 3 cases of Hodgkin's disease of the colon and rectum arising in patients with ulcerative colitis. (25 refs)

78-4094 **Longitudinal Studies of Chromosomal Abnormalities and Reticulum Cell Proliferation in New Zealand Black Mice.** (Eng) Friedman, J. M. (Medical Genetics Section, Medical Service, Veterans Admin. Hosp., Seattle, WA, 98108); Fialkow, P. J.; East, J.; Bryant, J. I.; Salo, A. C. *Int J Cancer* 22(4): 454-457; 1978.

Serial cytogenetic and histopathological examinations were performed on the spleens of 40 New Zealand Black (NZB) mice, an inbred strain susceptible to the development of clones of aneuploid (Anp) spleen cells and malignant reticulum cell proliferation, and 20 BALB/c control mice. A population of Anp cells was detected in direct spleen preparations from 10/36 NZB mice $\geq$6 mo old. Definite or possible reticulum cell sarcoma type B was diagnosed in 10/32 NZB mice $\geq$11 mo old but in only 1/34 younger mice. No neoplasms were found in control mice. In mice with both splenic Anp mosaicism and reticulum cell neoplasia, aneuploidy (Anpy) was found earlier than the neoplasia. Although there was no apparent association between splenic Anpy and neoplasia in single specimens obtained from NZB mice at various ages, there was a significant association between the occurrence of Anp mosaicism some time during life and the histological diagnosis of reticulum cell neoplasia in NZB mice $\geq$8 mo old. This finding is compatible with the hypothesis that Anp clones that arise in the spleens of aging NZBs are at least potentially neoplastic. The results indicate that inability to demonstrate chromosomal abnormalities in a direct preparation cannot be used as evidence against the presence of karyotypic alterations within the neoplastic cells themselves. (10 refs)

78-4095 **Neoplastic Behavior of Chromosomally Abnormal Clones in New Zealand Black Mice.** (Eng) Friedman, J. M. (Medical Genetics Section, Medical Service, Veterans Admin. Hosp., Seattle, WA, 98108); Fialkow, P. J.; Bryant, J.; Reddy, A. L.; Salo, A. C. *Int J Cancer* 22(4): 458-464; 1978.

The distribution of aneuploid (Anp) cells within the spleens and other organs of New Zealand Black (NZB) mice was determined and compared to that of neoplastic reticulum cells to define the relationship between neoplasms and chromosomal abnormalities. The results indicate that Anp cells arise focally and may remain so for > 1 mo. All 14 mice studied histopathologically had abnormal reticulum cell proliferation except one, a mouse with lymphocytic leukemia. Aneuploidy (Anpy) was found in the marrow, nodes, and spleen of this mouse. Four other mice had Anpy in nodes as well as in the spleen, but only 2/13 had Anpy in the marrow. Spleen cells were transplanted into newborn NZB recipients from 10 old NZB donors, 6 of which had obvious Anpy. In each instance, at least one recipient had splenic Anp mosaicism and/or reticulum-cell sarcoma before 7 mo of age. In every case in which spleen cell Anpy was found in a young recipient mouse, the abnormal population was apparently clonal and of donor origin. Spleen cells from the three donors without Anpy did not induce histological malignancy or splenic Anpy. As opposed to Anpy, no statistically significant association was found between histologically diagnosed reticulum cell sarcoma in a donor and the transplantability of its spleen cells. These and previous data strongly support the hypothesis that Anpy and neoplasia occur in the same population of spleen cels in NZB mice and suggest that karyotypic abnormalities may be important in the development of reticulum cell neoplasia in NZB mice. (11 refs)

78-4096 **Early Lymphatic Spread of Osteogenic and Soft-Tissue Sarcomas.** (Eng) Weingard, D. N. (Surgery Branch, NCI, Bethesda, MD, 20014); Rosenberg, S. A. *Surgery* 84(2): 231-240; 1978.

The records of all 374 patients (227 males and 147 females, aged 9 mo to 80 yr) with osteogenic and soft tissue sarcomas who had been referred to NCI from 1953 to 1977 were reviewed to determine the incidence of lymph node (LN) involvement. Of the 210 patients were definitive therapy at NCI, 143 underwent surgery than included regional LN groups. The LN's were enumerated in the pathology reports of 113 surgical patients. The 5-yr survival rate for the 113 was 32.7% as compared with 41.6% for the larger group of 210. Early LN involvement was found among 6/113 patients, although only 3 cases represented true metastases. Five of the six patients died within 25 mo of initial treatment. Seventeen patients underwent prophylactic LN dissection. Only one of these disections was positive for metastasis, and the survival rate in this group did not differ from that of the larger group. Although removal of clinically suspicious LN's is reasonable, there appear be little justification for treating clinically uninvolved draining regional LN's in patients with sarcomas other than childhood rhabdomyosarcomas. (66 refs)

78-4097 **Electron Microscope Analysis of Myogenic Neoplasms.** (Rus) Galil-Ogly, G. A. (Res. Roentgenoradiological Inst., Moscow, USSR); Krylov, L. M.; Poroshin, K. K. *Vopr Virusol* 40(2): 19-25; 1978.

In an attempt to evaluate the differential diagnostic criteria of myogenic sarcomas, specimens of leiomyoma of the skin arteries, esophageal leiomyoma, leiomyosarcoma (metastatic node in the lung), and rhabdomyosarcoma of the soft tissues of the shin were analyzed electron microscopically. The leiomyoma cells contained myofibrils with characteristic focal indurations, basal membrane, and clusters of pinocytic vesicles. The blastomatous cells of the differentiated leiomyosarcoma had a reduced number of pinocytic vesicles and a fragmented basal membrane. Both the leiomyosarcoma and the esophageal leiomyoma contained intercellular desmosome-like formations. Some rhabdomyosarcoma cells contained striated myofibrils. (10 refs)

78-4098 **Origin of Familial Malignant Melanomas from Heritable Melanocytic Lesions: "The B-K Mole Syndrome".** (Eng) Clark, W. H. (Dept. Dermatology, Hosp. Univ. Pennsylvania, 36th and Spruce St., Philadelphia, PA, 19104); Reimer, R. R.; Greene, M.; Ainsworth, A. M.; Mastrangelo, M. J. *Arch Dermatol* 114(4): 732-738; 1978.

A distinctive syndrome occuring in six families affected by familial malignant melanoma is described. Among the family members examined, 15/17 patients with melanoma and 22/41 nonmelanoma relatives had unique melanocytic moles, whose clinical and histological features have been designated the B-K mole syndrome. The clinical features include the presence of <10 to >100 prominent moles on the upper trunk and extremities and variability of mole size (5-15 mm), outline, and color combination. Histologically, B-K moles show atypical melanocytic hyperplasia, lymphocytic infiltration, delicate fibroplasia, and new blood vessels that occur within a compound nevus or de novo. The transformation of two B-K moles into malignant melanomas was documented photographically. Six unsuspected new primary cutaneous malignant melanomas were diagnosed during the study. These observations coupled with the photographic evidence of transformation demonstrate that the large moles of the B-K mole syndrome may be formal precursors of malignant melanoma. (12 refs)

78-4099 **Hormonal Activation of Adenylate Cyclase in Mouse Melanoma Metastatic Variants.** (Eng) Niles, R. M. (Div. Surgery, Boston Univ. Sch. Medicine, Room 908, Instructional Building, 80 E. Concord St., Boston, MA, 02118); Makarski, J. S. *J Cell Physiol* 96(1): 355-360; 1978.

The ability of hormones that interact with cell-surface receptors, ie, melanocyte stimulating hormone (MSH), ACTH, and prostaglandin E_1 (PGE_1), to activate a plasma membrane-bound enzyme, adenylate cyclase, was examined in intact mouse melanoma cells (B16 F_1, F_5, and F_{10}) of varying metastatic potential (MP). F_1 cells (low MP) had significantly greater cyclic AMP (cAMP) levels in response to all three hormones than F_5 (intermediate MP) and F_{10} (high MP) cells. The ranking of the response was: MSH, $F_1 > F_5 > F_{10}$; ACTH, $F_1 > F_5 > F_{10}$; PGE_1, $F_1 > F_{10} > F_5$. In contrast, the degree of hormonal stimulation of adenylate cyclase in broken cell preparations was virtually identical in all three melanoma cell lines. Control enzyme activity was depressed in both F_5 and F_{10} relative to F_1. The discrepancy between the ability of hormones to increase cAMP levels in intact vs broken cells could not be accounted for by differences in cAMP phosphodiesterase activity. However, it is concluded that the results from intact cells provide the best approximation to physiological mechanisms and hormone action and that as melanoma cells increase in MP, there is a significant loss in the ability of their cAMP system to respond appropriately to hormonal stimuli. (11 refs)

78-4100 **New Contributions to the Study of Endometriosis. Local Tissue Characteristics Favoring Growth of Endometrial Tissue. Study of 1,097 Cases.** (Fre) Jonesco, M. V. (3, Blvd. Dimitrie Cantemir, Bucharest, Rumania); Popesco, C. *Gynecologie* 28(6): 549-556; 1977.

Various tissue characteristics that favor the growth of endometrial tissue are presented. From 1955 to 1967, histological studies were performed on 1,097 patients with endometrioses. The most common site for ectopic endometrial growth was the fallopian tubes (513), followed by the uterus (445) and the ovary (110). Factors favoring endometrial tissue growth include diminished local tissue immunity, vascularization, and the presence of mucopolysaccharides and glycogen. (10 refs)

78-4101 **Gastrointestinal Polyposis in Multiple Myeloma.** (Eng) Goeggel-Lamping, C. (Cancer Inst., Hahnemann Medical Coll. and Hosp., Philadelphia, PA, 19102); Kahn, S. B. *JAMA* 239(17): 1786-1787; 1978.

A 69-yr-old woman had myeloma beginning as solitary plasmacytoma with progression to extensive skeletal and extraskeletal (gluteal region, gastrointestinal polyposis) involvement. The major clinical problems were related to the gastrointestinal tract lesions. Postmortem exam revealed involvement of the marrow, small bowel, mesenteric nodes, ovaries, uterus, kidneys, pancreas, and stomach. At presentation, there was no evidence of immunoglobulin abnormalities or Bence-Jones protein excretion, making this case unusual. (3 refs)

78-4102 **Condyloma Acuminatum of the Nipple.** (Eng) Wood, C. (Dept. Pathology, Room B-1265, Univ. Maryland Hosp., 22 S. Greene St., Baltimore, MD, 21201). *J Cutan Pathol* 5(2): 88-89; 1978.

A 20-yr-old male mental patient had viral condyloma acuminatum (CA) of the nipple with underlying Darier's disease that, because of its often exudative nature, may have contributed to the unusual location of the lesion. There were numerous papules of Darier's disease in the skin adjacent to the base of the papilloma, but changes characteristic of this disease and CA were not both present at the same point. (5 refs)

78-4103 **DNA Repair Processes in Human Cells (Meeting Abstract).** (Eng) Cleaver, J. E. (Lab. Radiobiology, Univ. California, San Francisco, CA, 94143). *Mutat Res* 53(2): 169; 1978. (no refs)

78-4104 **Excessive Mutational Occurrences in Wild Peruvian House Mice (Meeting Abstract).** (Eng) Wallace, M. E. (Dept. Genetics, Univ. Cambridge, London, England); Berry, R. J. *Mutat Res* 53(2): 282-283; 1978. (3 refs)

78-4105 **Basal Cell Carcinoma in Identical Twins (Letter to Editor).** (Eng) Kaprio, J. (Dept. Public Health Science, Univ. Helsinki, Helsinki, Finland); Teppo, L. *Br Med J* 2(6134): 436; 1978.

Basal cell carcinoma occurred in four pairs of identical male twins. The crude proband concordance rate in identical twins is much higher than the risk in the general population, but the common familial environment is a confounding factor that should be considered. (1 ref)

78-4106 **Electrophoretic Shift Mutants in Chinese Hamster Ovary Cells: Evidence for Genetic Diploidy.** (Eng) Siciliano, M. J. (Biology Dept., M. D. Anderson Hosp. and Tumor Inst., Univ. Texas System Cancer Center, Houston, TX, 77030); Siciliano, J.; Humphrey, R. M. *Proc Natl Acad Sci USA* 75(4): 1919-1923; 1978.

Chinese hamster ovary (CHO) cells were screened for electrophoretic shift variants of enzymes coded by approx 40 genetic loci to test the hypothesis of functional hemizygosity as a general theory to explain the expression of recessive mutations in CHO cells. Clones isolated after exposure to UV radiation were examined by starch gel and Cellogel electrophoresis. Shift variants were recovered for enzymes representing 11 different loci. Variant clones were subcloned to demonstrate the heritability of the variations. Mutants at nine loci produced multiple-banded patterns consistent with the patterns expected of genes at loci represented twice (diploid loci). Only one locus appeared to be functionally haploid. Chromosome localization of these diploid loci in other mammalian species where they have been mapped (mouse and man) suggests that they represent a random sample of CHO genes. Chromosome analysis of mutant subclones indicated that the variation did not occur in tetraploid cells. The data indicate that the quasi-diploid CHO cells are only as functionally hemizygous as would be expected of a slightly hypodiploid cell line derived from an organism in which the haploid number is 11. (33 refs)

78-4107 **Genetic Analyses of Differences in Incidence o Mammary Tumors and Reticulum Cell Neoplasms with the Use of Recombinant Inbred Lines of Mice.** (Eng) Dux, A. (Netherlands Cancer Inst., Sarphatistraat 108, Amsterdam C, Netherlands); Muhlbock, O.; Bailey, D. W. *J Natl Cancer Inst* 61(4): 1125-1129; 1978.

The influence of genes, in addition to genes in the *H-2* complex, that affect the mammary tumor incidence differences between BALB/c and B6 mice was studied with the use of seven recombinant inbred (RI) CXB lines. These lines are well-suited for investigation of the genetics of a trait for which the genotype affects probability of phenotype expression and which therefore is measured as incidence. Females of lines CXBD, CXBE, CXBG, CXBH, CXBI, CXBJ, and CXBK and their progenitor strains C57BL/6By (B6) and BALB/c-By (BALB/c) were inoculated ip with MuMTV at 3 mo of age and were force bred. They were observed for mammary tumors. The B6 strain was least susceptible, and mammary tumors appeared late in life. The BALB/c strain was most susceptible, and the tumors appeared early in life. The course of tumor development in the RI lines fell between these extremes. The RI strain distribution pattern of mammary tumor incidence indicated that at least one and probably several loci in addition to those at *H-2* determined the difference between the BALB/c and B6 strains. Effects of the other gene(s) appeared to be even more important than those of *H-2* The locations of these loci were not elucidated by this study. The spontaneous incidence of reticulum cell neoplasms was also recorded. The most frequent neoplasm was a Hodgkin's-like lesion. The data suggest an influence of the *H-2* complex. (9 refs)

78-4108 **Expression of Transformation in Cell Hybrids II. Nonsuppression of the Transformed Phenotype in Hybrids Between a Chemically Transformed and Nontransformed Derivatives of BALB/3T3.** (Eng) Jha, K. K. (Dept. Biological Sciences, Hunter Coll., CUNY, 695 Park Ave., New York, NY, 10021); Cacciapuoti, J.; Ozer, H. L. *J Cell Physiol* 97(2): 147-152; 1978.

Hybrids between a nitrosocarbaryl-transformed BALB/3T3 cell line, clone H, and a nontransformed cell line THO2, were studied. Both cell lines were derived from BALB/3T3 clone A31. Line THO2 is deficient in hypoxanthine-guanine phosphoribosyltransferase (HGPRT) and is resistant to cytotoxic concentrations of ouabain. Clone H exhibits morphologic and growth characteristics associated with the transformed phenotype: it grows to high saturation density, it is anchorage-independent, and it is able to form clones on monolayers of normal 3T3 cells. In contrast, THO2 retains growth properties characteristic of untransformed cells similar to the 3T3 parental cells. The deficiency of HGPRT, a recessive marker, and resistance of ouabain, a codominant marker, in THO2 allow selection of cell hybrids in medium supplemented with hypoxanthine, aminopterin, thymidine, and ouabain without the need for any induced selective markers in the other parent. The results show that these hybrid clones resemble the transformed parent in the clone morphology, higher saturation density, colony formation in medium with reduced serum concentration, growth in agarose, and ability to form clones on BALB/3T3 monolayers. The results are discussed in the framework of genetic models that permit or require dominant mutations for expression of the transformed phenotype. (33 refs)

78-4109 **Dysplastic Gangliocytoma of the Cerebellum - An Ultrastructural Study.** (Eng) Pritchett, P. S. (Cooper Green Hosp., 1515 6th Ave. S., Birmingham, AL, 35233); King, T. I. *Acta Neuropathol (Berl)* 42(1): 1-5; 1978.

Ultrastructural findings in a case of dysplastic gangliocytoma of the cerebellum are described. The patient was a 24-yr-old man who underwent surgery to remove a firm solid tumor that was diffusely infiltrating the right cerebellar hemisphere. Light microscopy revealed an enlarged cerebellar cortex with a densely staining outer zone and a pale inner zone. The outer zone was homogeneous, acellular and spongiotic, but the inner zone (granular layer) was cellular. Electron microscopy revealed that the granular layer was populated almost exclusively by large neurons 40-60μm in size. Cell shape was irregular and cell size variable. Intranuclear inclusions 1-2μm in size were seen infrequently. On high magnification, these inclusions were fibrillogranular in nature, and no viral bodies were identified. There was no evidence of a viral etiology for the disease. Both the light and electron microscopy findings support the theory that the abnormal neurons are hypertrophied granule cells. (13 refs)

78-4110 **Development of Cerebellar Malignant Astrocytoma at Site of a Medulloblastoma Treated 11 Years Earlier. Case Report.** (Eng) Kleriga, E. (Dept. Neurological Surgery, State Univ. New York, Downstate Medical Center, Brooklyn, NY); Sher, J. H.; Nallainathan, S. K.; Stein, S. C.; Sacher, M. *J Neurosurg* 49(3): 445-449; 1978.

A boy treated with surgery and radiation for a desmoplastic medulloblastoma of the left cerebellar hemisphere at age 10 mo developed a malignant astrocytoma at the site 11 yr later. It is not clear whether the second tumor represented a recurrence with differentiation or another primary. The origin of the second tumor is discussed in relation to general concepts of the genesis of medulloblastoma. (25 refs)

78-4111 **Growth of Human Gliomas in Immune-deficient Mice: A Possible Model for Pre-clinical Therapy Studies.** (Eng) Bradley, N. J. (Royal Marsden Hosp., Fulham Road, London S.W.3, England); Bloom, H. J.; Davies, A. J.; Swift, S. M. *Br J Cancer* 38(2): 263-272; 1978.

An attempt was made to provide an experimental system for screening cytotoxic and chemical radiosensitizing agents of possible value in the treatment of human gliomas and for studying the metabolism of human tumors. Thirteen gliomas from 55 neurosurgical specimens (11/25 derived from adults, 2/30 derived from children) were grown successfully after implantation (1-4 pieces/animal) into the sc flank tissue of immune-deprived or nude mice. The tumors were astrocytomas of Grades III and IV malignancy (9 adults, 1 child), medulloblastomas (1 adult, 1 child), and an oligodendroglioma from an adult. Tumor growth usually occurred several months after implantation; their human origin was confirmed by karyotypic analysis. The growth rates and histopathological picture of the initial specimens were maintained in initial and subsequent transplants, although future take rates improved in most instances. Primary human glioma tissues did not grow preferentially in nude mice, compared with immune-deprived mice. Preliminary observations suggest that these tumors in immune-reduced mice respond to agents that have been successful in humans. (15 refs)

78-4112 **Adenocarcinoma of the Nose and the Paranasal Sinuses: Association with the Woodworking Industry?** (Ger) Lobe, L. P. (Hals-Nasen-Ohren-Klinik, Bereich Medizin der Friedrich-Schiller-Universitat, Lessingstrasse 2, DDR-69 Jena, E. Germany); Ehrhardt, H. P. *Dtsch Gesundheitsw* 33(22): 1037-1040; 1978.

A detailed occupational history was obtained for 179/420 patients treated since 1931 at an ear, nose, and throat clinic in Jena, E. Germany, for malignant tumors of the nose and paranasal sinuses. Thirty-seven of the patients were woodworkers, a value that is high considering the percentage of the total population engaged in woodworking. Thirteen of the total 18 cases of adenocarcinoma occurred in these individuals ($p < 0.001$), who had worked under conditions of continuous exposure to wood dust for many years. The involvement of an exogenous factor in this type of cancer is supported by the facts that it is prevalent in the mucous membrane of the inner nose and ethmoid and that the disease occurs only after the age of 40. (13 refs)

78-4113 **Malignant Transformation of Laryngeal Papillomas.** (Jpn) Ishii, H. (Dept. Otorhinolaryngology, Gunma Univ., Sch. Medicine, Gunma, Japan); Kawabata, I. *J Otolaryngol Jpn* 80(3): 40-46; 1977.

A series of 32 patients (22 males and 10 females) treated for laryngeal papillomas since 1964 is described. Most of the patients were aged 30-59 yr; 10 were in their 60's, and 1 was < 10 yr old. The lesions appeared hyperkeratotic on laryngoscopy, and the child's lesions were not typical of the so-called multiple juvenile papillomas. Patients with localized papillomas were completely cured by surgery, but diffuse papillomas were resistant to radiotherapy or chemotherapy. Malignant transformation occurred in five patients (all men), with the interval between the onset of the symptom (hoarseness) and the transformation ranging from 4 to 9 yr. Laryngectomy was performed on all five patients, and three of the tumors were examined by serial large sections. In each case, the tumor extended to the underlying tissue, and in one case, it invaded the laryngeal cartilage. All patients survived without evidence of recurrence or metastasis. (9 refs)

78-4114 **Association Between Pulmonary Tuberculosis and Bronchial Carcinoma (Letter to Editor).** (Eng) Howie, A. J. (Dept. Pathology, Medical Sch., Birmingham B15 2TJ, England). *Lancet* 1(8089): 881; 1978.

A previously reported negative association between pulmonary tuberculosis and cancer of the bronchus is contradicted. It is currently thought that they coexist commonly, and probably more often than expected by chance. Although the exact frequency at which active tuberculosis occurs with lung cancer is not known, one study indicated that men who had tuberculosis had a higher than expected death rate from bronchial carcinoma. It is suggested that the cancer may reactivate the tuberculosis. (5 refs)

78-4115 **Enhancing Effect of Thoracotomy on Tumor Growth in Rats.** (Eng) Hattori, T. (Dept. Surgery, Res. Inst. Nuclear Medicine and Biology, Hiroshima Univ., Kasumi 1-2-3, Hiroshima 734, Japan); Hamai, Y.; Ikeda, H.; Harada, T.; Ikeda, T. *Gann* 69(3): 401-406; 1978.

To determine the influence of operative stress on tumor growth, thoracotomy (TC) and/or laparotomy (LO) were performed 48 hr after ip or iv inoculation of Sato lung cancer cells into Donryu rats. The size of the inoculum ranged from 2.5×10^6 to 10^3 cells for the ip route and from 10^5 to 10^2 cells for the iv route. Survival period, number of metastatic nodules on the surface of the lungs, and the percentage-area of metastases in the frontal section through the pulmonary hilus were examined. TC and LO+TC reduced the survival period of the tumor-inoculated rats significantly compared with control (nonoperated) rates, but difference between the two test groups was not significant. Also, there was no significant difference between the LO group and controls. The number and percentage-area of metastatic nodules were increased significantly by TC and LO+TC, but not by LO. Correlation between the number and the percentage-area of metastatic nodules was highly significant. The meaning of the stress of TC in cancer treatment is discussed. The enhancement of tumor growth by TC may depend on general host resistance rather than local factors. (15 refs)

78-4116 **Morphometric and Histological Analysis of the Lungs of Syrian Golden Hamsters.** (Eng Kennedy, A. R. (Dept. Physiology, Harvard Sch. Public Health, Boston, MA, 02115); Desrosiers, A.; Terzaghi, M.; Little, J. B. *J Anat* 125(3): 527-553; 1978.

Adult male Syrian golden hamster lung morphometry and histology were studied in an attempt to determine differences between hamster and human lungs that may have relevance for lung carcinogenesis studies. Morphometric measurements were made on fresh lungs, lung casts, and histological sections. Since the epithelium is the site of origin of most human lung cancers, numbers and types of epithelial cells in the various regions of the lungs were determined using 1-μm plastic (glycol methacrylate) and electron microscopic sections. The principal morphometric difference between hamster and human lung models resides in the declining surface area of peripheral airways encountered in the hamster lung. The decreases in length, diameter, and number of airways seen in the hamster lung combine to decrease the surface area in regions distal to the fifth generation. In models for the human lung, which have been developed and used to estimate particle deposition and clearance, the number of airways and surface area always increase as a function of generation. In its histological features the hamster trachea most closely resembles the human bronchus, the site of most human lung cancer. The types of mucous secretions produced by the lungs are different for the hamster and man, and these variations may influence the efficacy of the mucous ciliary escalator and alter the incidence and locations of tumors. Species variations in epithelial cell types may also affect tumor incidence. (56 refs

78-4117 **Localization of Bronchogenic Carcinoma in Tuberculous Lobes.** (Eng) Farwell, D. J. (87 Crystal St., New Orleans, LA, 70124); Rutledge, L. J.; Bryant, L. R.; Schechter, F. G. *South Med J* 71(4): 377-379 1978.

Twenty-seven cases of coexisting pulmonary tuberculosis and bronchogenic carcinoma were examined. Tuberculosis was confined to one or two lobes in 24/27 patients with coexisting disease; 21 of these patients had the neoplasm in a tuberculous lobe. Tuberculosis was diagnosed concurrently with carcinoma in 13 patients and 2-20 yr earlier in 12. It was confirmed 1 yr later than the cancer in one patient and 2 yr later in another. Carcinoma was diagnosed within 1 to 18 mo from hospital admission. When this series of 27 patients was combined with 11 other similar series, an av of 52% had the neoplasm in a tuberculous lobe. A low index of suspicion can delay diagnosis of the carcinoma until hilar enlargement, tumor, or metastasis is apparent radiologically. By then, the tumor has often become inoperable. It is suggested that carcinoma should be suspected in a tuberculous man of cancer age who smokes and who has a lesion that is enlarging, is in an unusual location, or is drug resistant. Cytologic study of sputum, bronchoscopy, and early thoracotomy are advocat ed. It is concluded that bronchogenic carcinoma has a striking predilection for a lobe of the lung that is or has been the seat of tuberculous infection, the most likely explanation being that this is scar carcinoma. (16 refs)

78-4118 **Microcystic Adenomas of the Pancreas and Constitutional Abnormalities (Letter to Editor).** (Eng) Soloway, H. B. (Associated Pathologists, P.O. Box 14220, Las Vegas, NV, 89107). *Am J Clin Pathol* 70(3): 445-446; 1978.

A recent study provides additional evidence for a multiorgan tumor diathesis and endocrinopathy associated with pancreatic cystadenomas. In two series of pancreatic cystadenoma patients, the combined incidence of thyroid cancer was 6.25% and that of renal cell carcinoma was 3.1%. (1 ref)

78-4119 **Duodenal Carcinoid with Cytoplasmic Whorls of Microfilaments.** (Eng) Carstens, P. H. (Dept. Pathology, Univ. Louisville Sch. Medicine, P.O. Box 1055, Louisville, KY, 40201); Broghamer, W. L. *J Pathol* 124(4): 235-238; 1978.

An unusual ultrastructure was found in a duodenal carcinoid in a 51-yr-old black man: most of the cells contained juxtanuclear whorls of microfilaments. This unique feature is described and discussed in relation to the cellular origin of this type of carcinoid. The filaments had a thickness of 8-10 nanometers (nm), and they very frequently occupied a large portion of the cytoplasm. Another prominent cytoplasmic feature was ubiquitous electron-dense, round granules. These granules, which had a diameter of approx 200 nm and were incompletely surrounded by unit membranes, were considered secretory granules. Some of the microfilament whorls contained the electron-dense granules and, in addition, centrosomelike structures. None of the tumor cells appeared to have microvilli. Similar microfilaments have been found in the D_1 cell of the gastroenteropancreatic endocrine system, and apparently identical whorllike accumulations of filaments have been described previously in the bronchial cells of animals treated with nitrosamines and in human giant cell carcinoma of the lung. It is suggested that the D_1 cell is the cell of origin for the duodenal carcinoid as well as for the above-mentioned lung tumors. (16 refs)

78-4120 **Hyperplastic Foci in Precancerous Rat Liver: Light Microscopic and Electron Microscopic Study.** (Eng) Timme, A. H. (Dept. Pathology, University Cape Town Medical Sch., Cape Town, S. Africa). *J Natl Cancer Inst* 61(2): 407-409; 1978.

Five hyperplastic foci (≤ 1 mm in diameter) induced by dimethylaminoazobenzene (DAB) in the siderotic livers of male Wistar-derived albino rats were investigated by light and electron microscopy. Rats were fed a basic maize diet containing 4% ferric citrate (wt/wt) for 2 mo, at which time the compound was removed and DAB was added (0.5%, wt/wt). The hepatocytes in the foci were larger than the surrounding cells, and they had a granular, moderately basophilic cytoplasm. Most were iron-free, although some Kupffer's cells contained hemosiderin. There were heavy deposits of iron in surrounding cells, possibly due to a defective storage mechanism in the foci cells. Under the electron microscope, the hepatocytes were shown to be well-differentiated, as evidenced by the presence of a well-developed rough endoplasmic reticulum, numerous free ribosomes, peroxisomes, Golgi bodies, bile canaliculi, and cytoplasmic junctional complexes. Thus, they resembled normal hepatocytes. Occasional ferritin-laden lysosomes persisted in some cells. In contrast, the proliferating cells of hyperbasophilic foci are poorly differentiated and bear no resemblance to normal hepatocytes. (8 refs)

78-4121 **Wilms' Tumor and Adrenocortical Carcinoma with Hemihypertrophy and Hamartomas.** (Eng) Muller, S. (Dept. Pediatrics, Freie Universitat Berlin, Heubnerweg 6, D-1000 Berlin 19, W. Germany); Gadner, H.; Weber, B.; Vogel, M.; Riehm, H. *Eur J Pediatr* 127(3): 219-226; 1978.

The case report of a 14-yr-old girl with hemihypertrophy and hamartomas who successively developed Wilms' tumor and adrenocortical carcinoma is presented. She developed the Wilms' tumor at age 2 yr, 11 mo, and, after nephrectomy, was given 3,000 rads to the right renal fossa and 12 courses of actinomycin D over 2 yr, 10 mo (total dose, 16 mg). At age 7 yr, 6 mo, she presented with rapid development of pubic hair, marked hypertrophy of the clitoris, acne vulgaris, and a sudden growth spurt. Plasma testosterone was increased markedly. An adrenocortical carcinoma was detected by arteriography at the site of the previously irradiated area, and it was removed. The girl also had hemihypertrophy (marked in the tongue), and hamartomas of the right occipital region and of the left forearm had been removed surgically at the end of the first year of life. Her parents and members of her father's family also have hamartomas. The occurrence of the two tumors with hemihypertrophy, hamartomas and advanced physical development supports the hypothesis that certain cases of Wilms' tumor and of adrenocortical carcinoma have common etiological factors, which are both teratogenic and oncogenic. Moreover, this case may provide another link between the hemihypertrophy syndrome and the EMG (exomphalos, macroglossia, and gigantism) syndrome. An alternative explanation of the induction of the second tumor by the previous radio- and chemotherapy is also given. (37 refs)

78-4122 **The Metastatic Spread of Cancers of the Digestive System in Man.** (Eng) Viadana, E. (Dept. Health, Roswell Park Memorial Inst., 666 Elm St., Buffalo, NY, 14263); Bross, I. D.; Pickren, J. W. *Oncology* 35(3): 114-126; 1978.

The most common disseminating routes for the spread of primary cancers of the human digestive system were determined by statistical analysis of autopsy reports of 58 patients with pancreatic adenocarcinomas, 143 with stomach cancer, 165 with colon cancer, and 150 with rectal cancer, all collected between 1956 and 1966. The cascade spread of metastases (previous seeding of 1 or 2 key organs is required for the disease to spread from the primary tumor throughout the body) is more common than a direct spread. With the exception of the rectal adenocarcinomas, it appears that the liver cascades metastasize to the lungs and that this is the most common route for the dissemination of metastases to the lungs. The abdominal and pelvic nodes are not responsible for the seeding of the liver. The lungs alone or the liver and lungs together very often disseminate blood-borne metastases to the thyroid, pituitary, CNS, vertebrae and other bones, kidney, adrenal glands, and spleen. For other organs, such as the ovaries, uterus, ureters, stomach, small and large intestines, pancreas, and extrahepatic biliary tract, metastases seem to originate directly from the primary cancer in 50% of the cases. In the other 50%, metastases may originate in the lungs alone or in both the liver and lungs. It is concluded that the closer the metastatic organ to the primary cancer, the less important the role of the lungs and liver in disseminating metastases to those organs. (7 refs)

78-4123 **Experimental Colo-rectal Tumours in the Rat.** (Eng) Lindstrom, C. G. (Dept. Pathology, Univ. Lund, General Hosp., Malmo, Sweden). *Acta Pathol Microbiol Scand (A)* Suppl 268: 1-75; 1978.

The induction of colorectal tumors in rats by 1,2-dimethylhydrazine and N-methyl-N'-nitro-N-nitrosoguanidine is reviewed. Comparison of sequential findings in studies of serum-blocking activities in tumor-bearers with those of double-contrast radiography and histopathologic examinations showed that the immunologic test for tumor detection is specific and reliable. (85 refs)

78-4124 **Primary Malignant Melanoma of the Small Intestine and the APUD Cell Concept.** (Eng) Krausz, M. M. (Dept. Surgery, Hadassah Univ. Hosp., Kiryat Hadassah, Jerusalem, Israel); Ariel, I.; Behar, A. J. *J Surg Oncol* 10(4): 283-288; 1978.

The case report of a 70-yr-old woman with primary melanoma of the small intestine is presented. It is suggested that this tumor could have arisen from APUD (amine precursor uptake and decarboxylation) cells derived from the neural crest. (18 refs)

78-4125 **Precancerous Changes and Histogenesis of Cancer of the Stomach.** (Rus) Dikshtein, E. A. (Dept. Pathoanatomy, Medical Inst., Gorki, USSR); Vasilenko, I. V. *Vopr Onkol* 24(7): 22-29; 1978.

The relationship between the type of precancerous change i the stomach and the histogenesis of stomach cancer was studied in 142 stomach cancer patients, 20 patients with chroni gastric ulcer, and 800 patients with chronic gastritis. Amon the cancer patients, 47 had highly differentiated adenocarcinomas, 73 had undifferentiated carcinomas, and 22 ha mixed carcinomas. Analysis of the gastric mucosa showe that 39/47 adenocarcinoma patients had severe symptoms c atrophic gastritis, compared with 12/73 patients with undi ferentiated carcinomas. The undifferentiated carcinoma patients had an increased frequency of chronic gastric ulcer (50/73, compared with 12/47 adenocarcinoma patients Proliferation of the gastric pit epithelium was observed in th gastritis patients and proliferation of the glandular epithel um, particularly of the glandular ducts, was observed in th gastric ulcer patients. These findings confirmed the association of gastritis with adenocarcinoma and of ulcers with ur differentiated carcinomas. (32 refs)

78-4126 **Influence of Duodenogastric Reflux on the Induction of Cancer of the Gastric Stump.** (Ger Dahm, K. (Chirurgische Universitatsklinik, Martinistrass 52, 2000 Hamburg 20, W. Germany); Schreiber, H. W Werner, B.; Knipper, A.; Mitschke, H. *Inn Med* 4(7 297-302; 1977.

The effect of duodenogastric reflux on the incidence of carcinomas near a gastroenteric (GE) anastomosis was studie in 72 male Wistar rats. Group I consisted of 39 rats wh underwent a short-loop anastomosis (Billroth II), which resulted in reflux of the bile and duodenal secretions into th remaining stomach. A Y-shaped GE (Roux) techniqu which delivers the bile and pancreatic juices directly into th jejunum without contacting the stomach, was used for 33 rat (Group II). The control group (27 rats) had no surgical trea ment. N-Methyl-N'-nitro-N-nitrosoquanidine (MNNG: 12 mg/liter drinking water) was given to all groups for 33 wl One week after the end of MNNG exposure, 13/22 Grou I rats had malignant tumors: 11 had adenocarcinomas, 2 sarcomas. The most common histological type of adenocarcinoma was the intestinal type, according to the new nomenclature. Carcinomas were found in 7/21 Group II rats, 4/2 Group III rats. There was also one sarcoma in the latter. Th incidence of malignancy in Group I was significantly highe ($p < 0.05$) than that in Group II. Thus, duodenogastric reflu increases the incidence of cancer in the resected stomach an small intestine of rats. Patients who have had an anastomos that permits this type of reflux should be considered high-ris and should be followed with x-ray and endoscopic stud Surgery for stomach ulcers should employ techniques whic do not allow duodenogastric reflux. (10 refs)

78-4127 **Hypercalcemia Associated with Uroepithelia Neoplasms.** (Eng) Mandell, J. (Dept. Surgery Div. Urology, Univ. North Carolina Sch. Medicine, Chape Hill, NC); Magee, M. C.; Fried, F. A. *J Urol* 119(6): 844-845 1978.

Three recent cases of transitional cell carcinoma associated with significant hypercalcemia are described. Each of the patients (2 men 57 and 66 yr old, 1 woman 60 yr old) had histologically proved transitional cell carcinoma of the bladder and/or renal pelvis, markedly elevated serum calcium levels, a negative bone scan, and elevated parathormone levels. In the one patient in whom surgical extirpation was possible, there was an immediate and dramatic decrease in serum calcium to a normal level. Hypercalcemia without known bone invasion has previously been documented in 2 cases of transitional cell tumor, 2 cases of epidermoid carcinoma of the bladder, and 3 cases of bladder carcinoma, histologic cell type unknown. The synthesis of a parathormonelike polypeptide by the neoplastic tissues appears to be the most likely mechanism for the production of hypercalcemia in all of these cases. The hypercalcemia of neoplastic disease is more severe than that of primary hyperparathyroid disease. (10 refs)

78-4128 **Starch Granuloma of the Urinary Bladder.** (Eng) McLean, P. A. (Dept. Urology, Jervis St. Hosp., Dublin 1, Ireland); Doyle, G. D.; Komaranchat, A. *Ir Med J* 71(1): 13-14; 1978.

A starch granuloma of the urinary bladder occurred in a 9-yr-old girl as a result of tissue contamination by the corn starch used as a surgical glove lubricant during a bilateral ureteroneocystostomy. A prominent granulomatous reaction was found 3 wk later upon biopsy prompted by pyrexia, bladder pain, and urinary leakage through the wound. (18 refs)

78-4129 **Chromosome Constitution of Gestational Trophoblastic Disease (Letter to Editor).** (Eng) Jacobs, P. A. (Dept. Anatomy and Reproductive Biology, Univ. Hawaii Sch. Medicine, Honolulu, Hawaii, 96822); Hassold, T. J.; Matsuyama, A. M.; Newlands, I. M. *Lancet* 2(8079): 49; 1978.

The chromosome set of cells from four patients with trophoblastic disease (3 hydatidiform moles, 1 possible malignancy) was studied. The first three patients had a 46,XX chromosome set, and they responded well to therapy. The fourth patient had an extremely abnormal karyotype (none of the trophoblasts had 46 chromosomes), and the cells were clearly androgenetic in origin. Although the cytogenetic evidence might indicate clinically over malignancy, there was no evidence of frank malignancy. Sections contained a mixture of normal- and abnormal-appearing villi. (no refs)

78-4130 **Vestigial Cells in the Endoexocervical Transition Zone. Optical and Ultrastructural Study.** (Fre) Hoang-Ngoc Minh (Laboratoire d'Anatomie Pathologique, C.H.U. d'Amiens, Amiens, France); Lecomte, D.; Coupez, F.; De St Maur, P. P.; Smadja, A.; Orcel, L. *Gynecologie* 28(6): 523-527; 1977.

A light and electron microscope study was made of tissue samples from the cervix of normal women, free of cervical lesions, in their reproductive period. Biopsies were taken from the exocervical periorificial ring, and all zones of typical or atypical cicatrization were eliminated from study. The endoexocervical transition zone is not constant in size (range 1-10 mm) around the cervix. Using colposcopy with fluorescent dyes, the islands of vestigial cells could be seen as tiny iodonegative plaques. Light and electron microscopy identified these cells as malpighian, which relates them to the germinal cells of the basal layer of the exocervical malpighian epithelium. The vestigial cells are "sandwiched" between the malpighian epithelium and the cylindrical cell epithelium of mullerian origin. They are the vestigial elements of the cranial portion of the epithelial layer of sinus origin that contributed to the formation of the exocervical and vaginal malpighian epithelium. It is hypothesized that these cells are usually quiescent but under the influence of certain stimuli, they will proliferate, giving rise to cervical dysplasia or carcinoma in situ. (22 refs)

78-4131 **Adipose Tissue and Aetiology of Breast Cancer (Letter to Editor).** (Eng) Adami, H. O. (Dept. Surgery, Univ. Hosp., S-750 14 Uppsala, Sweden); Rimsten, A. *Lancet* 2(8091): 677-678; 1978.

The results of a case-control study of 179 unselected breast cancer patients and 179 age-matched controls do not support the hypothesis that the amount of adipose tissue, as reflected in breast size, is related to breast cancer risk. However, mean serum levels of estrone and androstenedione were higher in 122 postmenopausal breast cancer patients than in age-matched controls. There was no quantitative influence of adipose tissue on these levels. (1 ref)

78-4132 **Cancer Risk in Patients with Congenital Polycystic Kidney.** (Ita) Ribacchi, R. (Universitario di Medicina, Perugia, Italy); Berardi, C. *Lav Ist Anat Istol Patol (Peru* 3(1): 5-16; 1978.

From 1947 to 1977, 45 cases of congenital polycystic kidney (CPK) were found in an autopsy series of about 12,000 at Pisa University Hospital, Pisa, Italy. Tumors were found in 6/45 cases, without any sex bias. Median age at death was 71 yr among the 6 tumor-bearing patients and 57 yr among the 39 tumor-free patients. Analysis of these 45 cases and the 196 cases reported in the literature showed that the tumors usually develop in subjects > 50 yr of age and that they are preferably localized to the esophagus, stomach, rectum, bile ducts, kidney, and urinary bladder in men and to the ovaries, breast, and external genitals in women. The findings indicate a relationship between CPK and tumors. Compared with the general population, tumor risk is increased 23-fold in men with CPK and 12-fold in women with CPK (25-fold in men and 28-fold in women in the present series). Immunosuppression, possible exposure to endogenous carcinogens, and, especially, a genetic factor are hypothesized as the possible causes of the significantly increased tumor incidence in CPK patients. (22 refs)

78-4133 Condyloma Acuminata and Cancer of the Vulva, Vagina, and Penis. (Ger) Schmauz, R. (Abteilung fur Pathologie der Med. Hochschule, Ratzeburger 160, 2400 Lubeck, E. Germany); Elsasser, E.; Lalwak, A.; Cordes, B. *Geburtshilfe Frauenheilkd* 38(5): 342-351; 1978.

Among biopsy specimens examined in Lubeck, East Germany, between 1947 and 1976, condyloma acuminata (CA) were associated with 11/21 vaginal carcinomas, 50/71 vulvar carcinomas, and 10/49 penile carcinomas. In most cases, the CA preceded the carcinomas by decades; in the vulva, however, there was a second group of lesions that preceded by the carcinomas by only a few years. There were four cases of mixed forms showing various stages of malignant degeneration of CA. Additional lesions seen were Bowen's disease, giant condyloma, verrucous carcinoma, and overt squamous cell carcinoma. Case reports recording malignant transition after 20-30 yr and geographic correlations observed in Uganda support the concept that CA occurring in the young are precancerous lesions with a low risk of malignant transformation. Accordingly, CA occurring in older patients could be precancerous lesions with a relatively high risk of transformation. Nonetheless, the risk may be independent of age factors in a small percentage of CA patients. It is suggested that variants between acuminata and giant condyloma should be termed condyloma only. Additionally, the term dysplastic should be used as an indication of the high risk associated with these variants. The possibility that the condyloma virus is involved in the etiology of genital cancer is discussed. (28 refs)

78-4134 Rapid Development of Malignant Metastases in the Abdominal Wall after Laparoscopy. (Eng) Dobronte, Z. (First Dept. Medicine, Univ. Medical Sch., H-6701 Szeged, Hungary); Wittmann, T.; Karacsony, G. *Endoscopy* 10(2): 127-130; 1978.

A bilateral cystadenocarcinoma of the ovary in a 52-yr-old woman metastasized rapidly to the wounds of the abdominal wall made by laparoscopy. The metastases were generated by penetration of ascites containing tumor cells into the wound of the parietal abdomen. (10 refs)

78-4135 Second Primary Neoplasms Following Ovarian Cancer. (Eng) Reimer, R. R. (Dept. Hematology and Medical Oncology, Cleveland Clinic Foundation, 9500 Euclid Ave., Cleveland, OH, 44106); Hoover, R.; Fraumeni, J. F.; Young, R. C. *J Natl Cancer Inst* 61(5): 1195-1197; 1978.

Data on second primary neoplasms in women treated for ovarian cancer were obtained from the end results progra (ERP) of the National Cancer Institute, which include 13,309 ovarian cancer patients treated between 1935 an 1972, and from a survey of 5,455 patients treated with a kylating agents between 1970 and 1975 at 70 institutions. Th expected numbers of second cancers in the ERP group ca culated by applying age-, sex-, and time-specific incidenc rates from the general population to the corresponding pe son-years of follow-up in the ovarian cancer patients (rate used were from the Connecticut tumor registry). The expec ed numbers of second cancers in the other group were ca culated by applying age- and sex-specific incidence rates o tained in the Third National Cancer Survey to the numbe of person-years at risk. In both groups, there was an increase risk of cancer of the uterine corpus, colon, bladder, breas and hemopoietic system. The excess risk of uterine corpu cancer was independent of therapy. The risk of colon cance was increased in all treatment groups but was particular high among patients who had received radiation or chemoth erapy. The predisposition to other neoplasms was limited certain treatment groups: bladder cancer to radiation, le kemia to chemotherapy, and lymphoma to radiation chemotherapy. Thus, the pattern of second neoplasms follo ing ovarian cancer appears as common etiologic factors. (1 refs)

78-4136 **Childhood Cancer in Sweden, 1958-1974. I. Incidence and Mortality.** (Eng) Ericsson, J. L. (Central Lab. Clinical Pathology, Univ. Hosp., Univ. Uppsala, Uppsala, Sweden); Karnstrom, L.; Mattsson, B. *Acta Paediatr Scand* 67(4): 425-432; 1978.

Analyses were made of all cases of tumors and tumor-like conditions in children 0-14 yr old reported to the Swedish cancer registry during 1958-1974. The material consisted of 3,797 individuals. The most common cancer diagnoses were leukemia and CNS tumors, both of which constituted approx 58% of all cases. Almost half of the cancers affected children < 5 yr old. The lowest incidence occurred at age 7-8 yr, the highest during the first year of life. In addition to neuroblastomas, Wilms' tumors, and retinoblastoma, certain uncommon tumors occurred at a high frequency during the first year of life. These included primary liver tumors, vulvovaginal tumors, and reticuloses. During 1958-1974, the incidence of childhood cancer increased significantly but the mortality rates decreased slightly. Most of the increase was due to the increased incidence of nervous system tumors, especially in boys (sex ratio, 3:1). The decrease in mortality rates was most obvious with respect to Wilms' tumor, and leukemia in children 0-4 yr old. (13 refs)

78-4137 **Epidemiological Aspects of Gastric Cancer in Costa Rica.** (Spa) Miranda, M. (No affiliation given); Macaya, J.; Moya de Madrigal, L. *Acta Med Costarric* 20(3): 207-214; 1977.

An epidemiological study was made of 1,426 patients with gastric cancer diagnosed in Costa Rica between 1969 and 1973. Most of the patients were men (1,002), and most were from a low socioeconomic class (64.3%); 34.57% had a middle-class background, 1.05% an upper-class background. An unusual finding was that 80 of the patients were < 29 yr old; however, approx 75% of the men and 72% of the women were 40-69 yr old. Positive diagnoses were arrived at by combinations of radiography, endoscopy, laparotomy, and biopsy. The incidence of gastric cancer was highest in patients from impoverished, rural, mountainous areas; the incidence was much lower in urban areas and coastal settlements. It was noted that two towns in which the principal occupation was dairy farming had relatively low incidences. A few towns had markedly lower or higher incidences than those of neighboring towns; no apparent cause could be found for these variations. Analysis of the diet of Costa Ricans in relation to the geographical variations revealed that in areas with the highest levels of gastric cancer, the diet is high in carbohydrates and low in animal and vegetable proteins. (8 refs)

78-4138 **Sheep Tumours in North East Yorkshire. I. Prevalence on Seven Moorland Farms.** (Eng) McCrea, C. T. (Veterinary Investigation Centre, West House, Thirsk, Yorkshire, England); Head, K. W. *Br Vet J* 134(5): 454-461; 1978.

The results of a mortality survey covering sheep on seven farms situated in northeast Yorkshire are reported. Between 1964 and 1977, 86 tumors were found in 62 sheep, an unusual geographical cluster of high prevalence. However, these figures may be underestimates, as a large number of sheep > 2 yr old died each yr, but only one-fourth of these were available for postmortem examination. In addition, several animals were sold and not traced further. There were 45 fibrosarcomas (41 in the jaw); 14 papillomas in the rumen; 7 squamous cell carcinomas (6 in the upper alimentary tract), 14 adenocarcinomas of the intestine, 3 primary carcinomas of the liver, 2 localized lymphosarcomas, and 1 epithelial thymoma. The percentage of tumors found at routine disease investigations in the rest of north Yorkshire during 1960-1968 was 0.9% in 2,398 carcasses. (23 refs)

78-4139 **Cancer Incidence in 1975 in the French Region of Bas-Rhin.** (Fre) Schaffer, P. (Institut d'Hygiene et de Medicine Preventive, 4,rue Kirschleger, F67085 Strasbourg Cedex, France); Cayemittes, P. A.; Arfeux, F.; Kuntzmann, Y. *Bull Cancer (Paris)* 65(1): 9-18; 1978.

Data from a cancer registry established in 1975 in the Bas-Rhin region of France (population 883,000 persons) are reported. A total of 3,073 cancer cases were registered, with an incidence of 424/100,000 men and 309/100,000 women. Lung cancer was the most frequent cancer (17.1%) among men, followed by cancer of the rectum and colon (7.9%), cancer of the prostate (7.6%), and cancer of the stomach (6.0%). In the female population, breast cancer was the most frequent type (27.5%), followed by cancer of the uterus (9.3%) and cancer of the cervix (6.8%). The av age at diagnosis was 63.5 yr in men and 62.7 yr in women; 95% of the cancers were diagnosed between the ages of 35-84 yr in men and 26-84 yr in women. The incidence of the most frequent cancers in the men and women of Bas-Rhin are compared with that reported in registries in Geneva, Sarre, Birmingham, Norway, and Connecticut. (5 refs.)

78-4140 **Cancer Mortality During the Last Twenty-five Years in Italy on Sardinia, with Special Regard to the City of Cagliari.** (Ita) Meloni, F. (Insituto Igiene, Cagliari, Italy); Dodero, G.; Contu, A. *Ig Mod* 70(1): 33-49; 1977.

Cancer mortality statistics are presented for Italy, Sardinia, and Cagliari, the capital of Sardinia. Overall cancer mortality (per 100,000 inhabitants) has increased from 52.77 in 1901 to 73.68 in 1931, 150.61 in 1960, and 192 in 1972. Mortality is highest in the densely populated and industrialized northern and central provinces and lowest in the underdeveloped southern provinces, being lowest in Calabria (98.7 in 1972) and highest in Emilia Romagna (289.5 in 1972). In 1951, mortality was 88 in Cagliari and 66.8 in Sardinia, vs 99.6 and 127.4, respectively, in 1971, a definite increase. In 1970, mortality in Sardinia and Cagliari was above the national for malignant tumors of the liver, bile ducts, trachea, and bronchi; mortality due to tumors of other organs was below the national av. Mortality was significantly lower among men than among women. The findings indicate an increase in cancer mortality in Sardinia and Cagliari that is parallel to the national trend. It may be related to the industrialization of the island. (no refs.)

78-4141 **Case-Control Study of Antihypertensive and Diuretic Use by Women with Malignant and Benign Breast Lesions Detected in a Mammography Screening Program.** (Eng) Williams, R. R. (Dept. Internal Medicine, Univ. Utah Medical Center, Salt Lake City, UT, 84132); Feinleib, M.; Connor, R. J.; Stegens, N. L. *J Natl Cancer Inst* 61(2): 327-335; 1978.

A case-control study of the association between breast cancer and the use of antihypertensive and diuretic drugs was conducted on subjects selected from among 80,000 women screened in a national mammography screening project. The study subjects consisted of 481 newly identified breast cancer patients group-matched with 1,268 controls and an additional case group of 421 women with benign breast lesions. Data were obtained by questionnaires sent to subjects and attending physicians. A significant but low-level association was revealed between breast cancer and the use of rauwolfia derivatives (reserpine) for ≥5 yr. This association was confined to women > 50 yr old who were also heavier than av. No confounding effects could be held responsible for this association after adjustment for variables such as presence of hypertension, wt, age at first pregnancy, and other breast cancer risk factors. Other antihypertensive and diuretic drugs as well as multiple drug use also showed some association with breast cancer (chlorthalidone, hydralazine, furosemide). There was a significant association between benign breast lesions and use of thiazides (for edema or hypertension) for ≥ 5 yr. Reserpine seemed to have a protective effect against breast cancer in short-term users, a finding consistent with observations in rats. These and previous data suggest serious consideration of long-term reserpine use as a cause of breast cancer. (16 refs.)

78-4142 **An Epidemiological Study of the Relationship Between Benign Breast Diseases and Breast Cancer (Meeting Abstract).** (Eng) Coombs, L. J. (John Hopkins Univ., Baltimore, MD, 21218) *Diss Abstr Int* 39(4): 1713-1714; 1978. (no refs.)

78-4143 **Epidemiological Aspects of Breast Carcinoma** (Rus) Chapliuk, M. I. (P. A. Hertsen Res. Oncological Inst., Moscow, USSR). *Khirurgiia (Mosk)* 4: 12-15 1978.

In an attempt to explain the heterogeneity of breast carcinoma incidence, 189 patients with mammary gland cancer and 137 healthy control women were asked to answer a specially devised epidemiologic questionnaire. The questionnaire contained > 350 questions on nationality, age, sexual history pregnancies, delivery, duration of lactation, etc. The only significant difference between the two groups concerned the lactation period: 28.94% of the women with breast carcinoma had lactation periods > 1 yr, compared with only 17.55% of the controls. (10 refs)

78-4144 **Estrogen Therapy and Endometrial Carcinoma** (Ger) Volker, W. (Frauenklinik der Medizinischen Hochschule Hannover, Pasteurallee, D-3000 Hannover 51, W. Germany); Kannengiesser, U.; Majewski, A.; Vasterling, H. W. *Geburtshilfe Frauenheilkd* 38(9): 735-743; 1978

The possible carcinogenic effect of estrogen compounds was studied in 130 women with endometrial carcinoma (EMC) (118 FIGO Stage I, 9 Stage II, 3 Stage III cases) and in matched controls. Matching traits were age at diagnosis and age at menopause, number of children and abortions, weight presence of diabetes, participation in cancer screening programs, educational level, use of heart drugs, antihypertonics or sedatives, blood pressure, and histological findings in addition to EMC (eg, glandular hyperplasia). All controls had been treated by curettage or hysterectomy for bleeding disturbances. All patients were questioned about estrogen usage and the relative risk (RR) was calculated by the method of Mantel and Haenszel. The RR found for the use of any estrogen was 0.44 ($p < 0.01$), and similar risks were found if the estrogens were separated into types (eg, conjugated, estriol, estradiol). The RR for estrogen-androgen mixtures was 1.28 ($p > 0.05$), that for inhibitors of ovulation, 0.1 ($p < 0.01$). There was no increased risk associated with duration of estrogen usage. Childless women who used estrogens had an RR of 0.34 ($p < 0.05$), users with high blood pressure had an RR of 0.23 ($p < 0.01$), and users who were obese had an RR of 0.30 ($p < 0.001$), indicating that estrogen usage may be protective for patients with these other known risk factors. The careful matching of the control group in this study may explain the finding of no increased risk of EMC due to estrogen usage. Several previous studies have shown an increased risk, but recent publications have indicated that as control matching improves, the risk decreases. (41 refs)

78-4145 **Urinary Tract Lesions and Analgesic Abuse.** (Ger) Brunner, F. P. (Departement fur Innere Medizin, Kantonsspital, CH-4031 Basel, Switzerland); Richtmann, L.; Thiel, G.; Dubach, U. C. *Schweiz Med Wochenschr* 108(27): 1013-1019; 1978.

A review of the records of the University Hospital in Basel, Switzerland, indicated that 20 patients with analgesic nephropathy and tumors of the urinary tract (excluding hypernephroma) were admitted between 1966 and 1976. There were 17 uroepithelial tumors, 2 sarcomas, and 1 chorioepithelioma. Phenacetin, a common ingredient of analgesic mixtures, is regarded as being carcinogenic on the basis of the structural similarity of some of its metabolites to industrial carcinogens and the results of animal experiments. Malignant tumors have been induced in animals by the 2-hydroxylated metabolites and arene oxides of phenacetin and paracetamol. There is even more convincing evidence of the carcinogenicity of the N-oxidized metabolites, such as N-hydroxyphenetidine and N-hydroxyphenacetin. Comparison of analgesic mixtures used in Australia and Sweden (countries with high rates of analgesic abuse) suggests that dimethylnitrosamine formed from aminophenazone does not play a role in the development of uroepithelial tumors. (46 refs)

78-4146 **Sperm Basic Proteins in Cervical Carcinogenesis (Letter to Editor).** (Eng) Issidorides, M. R. (Marine Biological Lab., Woods Hole, MA, 02543). *Lancet* 2(8091): 688; 1978.

Contradictory results of two studies relating sperm basic proteins to socioeconomic status and, in one, to cervical cancer may be due to the fact that subjects in one study were not screened for the use of psychotropic drugs, which reversibly increase, at least in peripheral blood cells, certain histone basic protein fractions. (2 refs)

78-4147 **Cancer of the Cervix--A Sexually Transmitted Disease. Cytologic Screening in a Prostitute Population.** (Eng) Sebastian, J. A. (Duluth Clinic, Ltd., 400 E. Third St., Duluth, MN, 55805); Leeb, B. O.; See, R. *Am J Obstet Gynecol* 131(6): 620-623; 1978.

Cervical cytology was performed at the time of required gonorrhea screening in 750 registered prostitutes in Taipei, Taiwan to determine whether cervical cancer can be transmitted sexually. This population was unique because the variables frequent intercourse with multiple partners and frequent infections could be separated from early intercourse (before the age of 18), which is socially and morally unacceptable in Taiwan. A clinical data sheet concerning age, length of employment, frequency of intercourse, contraception, and pregnancy history also was completed. The cytologic results were: normal in 253, mild inflammation in 426, inflammatory atypic in 33, dysplasia in 7, and suspicious in 1. Suspicious or positive cytology was found in only 8/750 prostitutes, for a rate of 10.7/1,000. This low yield of abnormal cytology suggests that early coital activity is the most important epidemiologic risk factor in the development of cervical cancer and that frequent intercourse with multiple partners and multiple infections are not important epidemiologically if they occur after the period of active metaplasia found during adolescence or during the first pregnancy. (21 refs)

78-4148 **Sperm Basic Proteins in Cervical Carcinogenesis: Correlation with Socioeconomic Class.** (Eng) Reid, B. L. (Dept. Obstetrics and Gynaecology, Univ. Sydney, New South Wales 2006, Australia); French, P. W.; Singer, A.; Hagan, B. E.; Coppleson, M. *Lancet* 2(8080): 60-62; 1978.

An attempt was made to obtain circumstantial evidence for sperm basic proteins as carcinogens in squamous cervical cancer by relating them to social class and to epidemiological variables thought to be correlated with the onset of the disease. These variables are the incidence of veneral disease and the precedence of carcinoma in situ, both of which are highly correlated with social class. Single ejaculates were obtained from 202 Australian and English men, mostly outpatients at infertility clinics, but some healthy students. Each individual was assigned to one of five social classes. Two types of basic protein, a histone and a protamine, were separated from the ejaculates, and a ratio between their contents in a given number of sperm was established. The ratio varied widely among the men and it correlated directly with social class: the lower the class, the greater the proportion of protamine. Statistically similar correlations link social class with the incidence of venereal disease and of carcinoma in situ. Thus, the basic proteins of the sperm head, especially the protamines, may also have a role in the etiology of squamous cervical cancer. (27 refs)

78-4149 **Risk of Cervical Cancer among an Electrocoagulated Population.** (Eng) Kauraniemi, T. (Finnish Cancer Registry, Inst. Statistical and Epidemiological Cancer Res., Liisankatu 21B, SF-00170 Helsinki, Finland); Rasanen-Virtanen, U.; Hakama, M. *Am J Obstet Gynecol* 131(5): 533-538; 1978.

Data from a nationwide mass screening registry plus data on malignant cervical lesions reported to the Finnish Cancer Registry, both covering the years 1963-1972, were used to assess the risk of cervical lesions among women who had been subjected to electrocoagulation of the uterine cervix (EC group) and among the rest of the Finnish female population (N-EC group). During this period, 429,832 women were screened, 67,321 of whom had undergone EC. The procedure was performed mainly in women 25-34 yr old (56,909 subjects) and in married women (60,884). Compared with the EC group, N-EC group had a sixfold risk of frankly invasive carcinoma, a fourfold risk of carcinoma in situ or dysplasia gravis, and a twofold risk of dysplasia levis. The diagnostic accuracy of cytologic tests, compared with the histologic malignancy of the lesion, was better in the EC group. For unmarried women, the total risk of premalignant and malignant lesions was the same in both groups. However, the total risk of any cancerous lesion was approx four times greater among those N-EC than among those EC in the other marital groups (married, widowed, divorced). The frequency of *Trichomonas vaginalis* infection (TVI) was higher among all N-EC women, including healthy subjects and cancer patients. The prevalence rates (per 100,000) of premalignant and malignant lesions by EC treatment and by occurrence of TVI were: 1,193 (N-EC + TVI), 535 (N-EC - TVI), 394 (EC + TVI), and 138 (EC - TVI). The potential effect of EC in reducing cervical cancer may exceed the effect of organized mass screening programs. (16 refs)

78-4150 **Cause of High Risk of Cervical Cancer in Socially Unclassified Women.** (Eng) Sibary, K. (Dept. Social Res., Univ. Hosp. S. Manchester, Manchester, England); Burslem, R. W.; Wakefield, J. *Br J Cancer* 38(1): 166-168; 1978.

The social class distribution of women with abnormal cervical smears who had not previously been allocated to a specific social class because of incomplete data was determined. Previous comparisons of the percentage of abnormal smears in the various classes had indicated that the unclassified women had a higher rate of suspicious and positive smears than the classifiable women. Questionnaires were sent to a random sample of 300/71,000 unclassified women; 235 acceptable replies were received. Distribution of these 235 women by social class showed only small and insignificant differences from the distribution of all classifiable women with abnormal smears screened between 1971 and 1976. However, significant differences in distribution by marital status and age were apparent. The 235 women included a significantly greater proportion of widows and divorcees (15%) than the remainder of the screened population (3.1%), and significantly more women were > 60 yr old (6.9% vs 2%) or < 25 yr old (40% vs 18.4%). Thus, the excess of abnormal smears in the unclassified women was determined mainly by the large proportion of widowed/divorced and elderly women (high-risk groups). (6 refs)

78-4151 **Incidence of Cervical Cancer by Marital Status.** (Eng) Leck, I. (Regional Cancer Epidemiology Unit, Univ. Hosp. S. Manchester, Manchester M20 9BX, England); Sibary, K.; Wakefield, J. *J Epidemiol and Community Health* 32(2): 108-110; 1978.

The incidence of invasive cervical cancer by age and marital status was examined using census statistics and 1968-1971 cancer registry data for women who lived in Manchester, (England) Regional Hospital Board area. The disease was
relatively rare in the unmarried. Formerly married wome
were at a considerably higher risk than married women. Th
incidence was highest at the ages of 40-49 for widows an
40-59 for divorced women. The standardized incidence rati
was 0.42 for single, 1.04 for married, 1.12 for widowed, an
1.66 for divorced women. It is suggested that the higher inci
dence rate in divorced women and young widows is relate
to the association of cervical cancer with number of sexua
partners. (15 refs)

78-4152 **Paroxysmal Nocturnal Haemoglobinuria i
Thailand with Special Reference to an Associa
tion with Aplastic Anaemia.** (Eng) Kruatrachue, M. (Di
Haematology, Dept. Medicine, Siriraj Hosp., Mahidol Univ
Bangkok 7, Thailand, Wasi, P.); Na-Nakorn, S. *Br J Ha
ematol* 39(2): 267-276; 1978.

The characteristics of 85 cases of paroxysmal nocturna
hemoglobinuria (PNH) in Thailand were compared wit
those of 80 European (Eur) cases, and the association of thi
disease with aplastic anemia (AA) was explored. Thai PN
patients tended to be younger (56 were < 30 yr old) than th
Eur patients (only 25 were < 30 yr old), and 23 of the Tha
patients were women, compared with 47 in the Eur series
The clinical presentations of Thai PNH were generally indis
tinguishable from those of the Eur cases, except that com
plications attributable to arterial and venous thrombosis wer
rare in the former (2 patients); they are reportedly commo
in the latter. Analysis of 232 Thai cases of AA revealed tha
the age of onset was similar to that of PNH, but the propor
tion of women was higher (103/232). An aplastic marro
could be found in cases diagnosed initially as PNH or subse
quently, during the course of illness diagnosed initially a
AA. Both groups had the same clinical symptoms, and bot
had features of AA. Cases diagnosed primarily as AA\"com
plicated" by PNH could be divided into two categories; (I
after various intervals, patients enter a remission of severa
years' duration that is followed by typical PNH; (II) the clas
sical picture of AA dominates the entire course of the disease
and there is no remission period. AA dose not precede PN
in all cases. Of the 232 AA patients, 47 were found to b
positive for PNH RBC in an initial test, but not in repeate
tests. According to the somatic mutation theory, the associa
tion of PNH and AA might be based on the occurrence o
abnormal RBC clone(s) in the bone marrow in one of severa
ways. The factor involved in promoting or eliminating thi
clone seems to be sex-related, and it might be ethnic in origin
(18 refs)

78-4153 **Epidemiologic Assessment of the Viral Hypoth-
esis of Human Lymphomas and Leukemias**
(Eng) Khokhlova, M. P. (Lab. Leukemia Epidemiology an

Transfusion, Moscow 125167, USSR); Osechinskiy, I. V.
Martirosov, A. R.; Yashanova, N. D. *In: Advances in Com*

parative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977. Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 269-270; 1978.

Leukemia and lymphoma incidence in the rural populations of the Lithuanian SSR and the Minsk region of the USSR was studied to determine if there is a viral etiology for human hemoblastoses in these areas. Knox analysis of the data revealed a rise in probability of the appearance of a second case of the disease within 4.5 km of a given case within 1.5 yr. However, there was no increase in human hemoblastoses as a result of residence near dairy farms or resulting from contact with cattle. (no refs)

78-4154 **Familial Leukemia.** (Fre) Schmitt, T. A. (Institut de Recherchde sur les Maladies du Sang, Hopital Saint-Louis, 2,place du Dr. Fournier, F75010 Paris, France); Degos, L. *Bull Cancer (Paris)* 65(1): 83-88; 1978.

Literature on the genetic factors in acute leukemia is reviewed, and a study of familial incidence among 2,966 patients is reported. In the series of 2,966 patients, there were 26 patients from families with more than one affected member. The relative risk for a sibling of a leukemic patient is four times greater than that for the population at large. Parents of leukemic patients may also run a greater risk of developing the disease. The leukemia was usually of the same type in patients from the same family, and the onset of the disease occurred approx at the same age. There were 2 pairs of identical twins with the disease among the patients in this series and 28 pairs of twins in the literature, 13 pairs that were definitely identical and 5 that were probably so. The relative risk of a twin developing leukemia decreases as the age at onset in the affected twin increases. (20 refs)

78-4155 **Subsequent Cancer in Patients with Chronic Lymphocytic Leukemia--A Possible Immunologic Mechanism.** (Eng) Greene, M. H. (Environmental Epidemiology Branch, NCI, NIH, Bethesda, MD, 20014); Hoover, R. N.; Fraumeni, J. F. *J Natl Cancer Inst* 61(2): 337-340; 1978.

The occurrence of a second primary cancer was examined among 4,869 white patients (3,094 men, 1,775 women) with chronic lymphocytic leukemia (CLL) diagnosed between 1935 and 1971. A second primary cancer developed in 234 CLL patients compared to 204.9 expected (Exp). The difference was due primarily to excesses of malignant melanoma [9 observed (Obs) vs 1.34 Exp], soft-tissue sarcomas (7 Obs vs 1.33 Exp), lung cancer (33 Obs vs 40.6 Exp). For several other sites (lip, salivary glands, tongue, Hodgkin's disease, and non-Hodgkin's lymphoma) the risk exceeded expectation, but the numbers were too small for further analysis. For the four main excess cancer sites, the excess risk affected both men and women, untreated and treated patients, and patients at all stages of follow-up. The finding of an excess risk throughout the follow-up period suggests an intrinsic association with CLL rather than an effect of methodology, diagnosis, or therapy. There was no excess risk of leukemia following the diagnosis of these second primary cancers, indicating a one-way association. This argues against a common etiology and suggests that a susceptibility state associated with CLL may underlie the development of a second primary cancer. These and similar previous data suggest that certain nonlymphoid tumors may result from impaired immunologic surveillance. (22 refs)

78-4156 **Cancer Incidence Amongst Cosmetologists (Meeting Abstract).** (Eng) Walrath, J. (Yale Univ., New Haven, CT, 06520). *Diss Abstr Int B* 39(4): 1714; 1978. (no refs)

78-4157 **A Case-Control Study of Hodgkin's Disease in Israel.** (Eng) Abramson, J. H. (Dept. Social Medicine, Hebrew Univ.-Hadassah Medical Sch., P.O. Box 1172, Jerusalem, Israel); Pridan, H.; Sacks, M. I.; Avitzour, M.; Peritz, E. *J Natl Cancer Inst* 61(2): 307-314; 1978.

A case-control study was made of 473 Jewish residents of Israel diagnosed as having Hodgkin's disease (HD) in 1960-1972 and matched controls drawn from the general population. There was a significant association between parental consanguinity and HD (14.1% of patients vs 8.4% of controls). Among men, the case-control difference was highly significant and the estimated relative risk of HD was 4.2, whereas among women the association was weaker and statistically nonsignificant. Associations between HD and a high educational level and the presence of a flush toilet and piped water in the childhood home were significant, giving limited support to the hypothesis that a high standard of living in childhood increases the risk of subsequent HD. Women with HD tended to have a lower parity than did their controls. Tonsillectomy and a history of work with wood or trees were significantly associated with mixed cellularity but not with other histologic subtypes. A weaker relationship was found between appendectomy and nodular sclerosis. Differences between HD patients and controls with respect to cigarette smoking, exposure to animals, marital status, previous blood transfusions or jaundice, contact with asbestos, and residental or occupational mobility were not significant. (37 refs)

78-4158 **Familial and Sporadic Hodgkin's Disease Associated with Occupational Wood Exposure (Letter to Editor).** (Eng) Greene, M. H. (Environmental Epidemiology Branch, NCI, Bethesda, MD, 20014); Brinton, L. A.; Fraumeni, J. F.; D'Amico, R. *Lancet* 2(8090): 626-627; 1978.

Occupational exposure to wood may have contributed to a familial concentration (3 sibs and a first cousin) of Hodgkin's disease. Two of the brothers had been employed (for 12 and 15 yr) by a cedar fence installation company, where they prepared and applied the wood preservative pentachlorophenol (PCP). One brother had high levels of PCP in serum (1,299 ppb) and urine (90 ppb). The other two afflicted family members had no such exposure. One unrelated employee of the same company also developed Hodgkin's disease. The fact that only 2/4 family members were occupationally exposed suggests that there is an interplay between genetic and environmental determinants. Occupational statements on death certificates were examined in North Carolina counties where furniture manufacturing and lumbering are common. Each of the 167 cases of Hodgkin's disease found between 1956 and 1974 were matched with two controls. An excess risk (1.4) was found only among occupational groups with wood and paper exposure. The major difference occurred for carpentry and lumbering, with a relative risk of 4.2. Use of PCP is common in many phases of wood processing. It is therefore suggested that the association between occupational wood exposure and Hodgkin's disease may be related to the use of particular wood preservatives. (12 refs)

78-4159 **Infectious Mononucleosis and Hodgkin's Disease.** (Eng) Munoz, N. (International Agency Res. Cancer, Lyon, France); Davidson, R. J.; Witthoff, B.; Ericsson, J. E.; de-The, G. *Int J Cancer* 22(1): 10-13; 1978.

A large follow-up study was made of 9,454 patients with serologically confirmed infectious mononucleosis (IM) to evaluate the association between IM and Hodgkin's disease (HD). The names of 1,759 patients identified in Scotland from 1959 to 1971 and 7,695 identified in Sweden from 1952 to 1970 were matched against the names of patients with lymphoma or nasopharyngeal or colon carcinoma registered through 1972 in Sweden and through 1973 in Scotland. There were 7 cases of HD among the IM patients (2 in men, 5 in women), compared with an expected number of 1.8, a fourfold increase in risk. The increased risk for HD was greater within 3 yr of IM diagnosis. These results are similar to those of four other cohort studies, and it is concluded that there is a positive association between IM and HD. Several explanations of the association are considered: some persons who are in the process of developing HD may be temporarily misdiagnosed as having IM; IM may increase the susceptibility of some individuals to a factor that causes HD; IM may promote the rapid (2-3 yr) development of HD in a subject in whom the disease is latent or progressing slowly; and IM and HD may have a common cause. 78-4160 **Epidemiological Features of Leukemia and Lymphoma and Other Malignant Hemopathies.** (Por) Jamra, M. (Disciplina de Hematologia do Departamento de Clinica Medica, Universidade de Sao Paulo, Sao Paul
Brazil). *Rev Braz Pesqui Med Biol* 11(1): 67-75; 1978.

Epidemiological data are presented on lymphomas and le
kemias in Brazil. Hodgkin's disease shows a unimodal distr
bution typical of underdeveloped countries. The risk
Hodgkin's disease is significantly increased among tonsille
tomized persons compared with their nontonsillectomize
relatives. In Brazil, Hodgkin's disease of lymphocy
predominance type accounts for 21.4% of cases, nodul
sclerosis for 7.2%, mixed cellularity for 64%, and lym
phocyte depletion type for 7.2%. In Sao Paulo, lymphosa
coma accounts for 10.53% of lymphoreticular tumor
reticulosarcoma for 17.2%, other lymphomas for 4.39%, le
kemias for 37.28%, Hodgkin's disease for 26.5%, Burkitt
lymphoma for 0.74%, and multiple myeloma for 3.36%
Epidemiological data are also given on the incidence of lym
phomas and leukemias in other parts of the world. (13 ref

78-4162 **Increased Incidence of Malignant Melanom**
after Peaks of Sunspot Activity. (Eng) Houghton, A. (Oncology Div., Dept. Medicine, Univ. Connecticu
Sch. Medicine, Farmington, CT, 06032); Munster, E. W.;
Viola, M. V. *Lancet* 1(8067): 759-760; 1978.

A review of 2,983 cases of histologically proved maligna
melanoma registered in the Connecticut Tumor Registry i
1935-1975 indicated that the age-adjusted incidence rate fo
malignant melanoma in that state has risen from 1.1/100,00
population in 1935 to 6.2/100,000 in 1975. Superimposed o
a steady rise in incidence are 3- to 5-yr periods in which th
rate of increase in incidence rises. These periods have a cycl
of 8-11 yr and follow times of max sunspot activity. In Ne
York state, like Connecticut, there were significant partia
correlations between the annual sunspot number and th
melanoma incidence rates in the following 1-2 yr. In Finlan
the increased incidence rates were significantly correlate
with the years of sunspot activity and with the first subse

uent year. The longer lag period between sunspot cycles and e cyclic increases in melanoma incidence in Connecticut d New York, compared to Finland, may be latitudinal and uld be important in constructing a mechanism of sun- ot-induced carcinogenesis. (26 refs)

8-4163 **Secondary Malignant Melanoma in Lymph Nodes: Incidence, Time of Occurrence, and ortality.** (Eng) Little, J. H. (Pathology Dept., Princess lexandra Hosp., Ipswich Road, Woolloongabba, Brisbane 102, Australia); Davis, N. C. *Aust NZ J Surg* 48(1): 9-13; 978.

atients registered in the Queensland Melanoma Project ustralia) with histologically proved secondary deposits of elanoma in the lymph nodes were studied. Of the 1,514 atients registered since 1963, 234 had metastases in their mph nodes by 1975: 146/685 men and 88/829 women. The v age for each sex was 50 yr. Among the fatal cases were 8 men and 54 women. Thirty-two patients had positive odes with no known primary lesion. Metastases developed men with lesions on the foot (50%), on the thigh (29%), nd on the back (22%) and in women with lesions on the wer leg (9%) and thigh (20%). Approx one-half of the odes were removed at the time of treatment of the primary rowth or within 2 mo; three-fourths were removed in the rst yr. However, it was found that a tumor could remain ormant for > 8 yr. On regrowth, the dormant tumors ehaved in a similar aggressive fashion as the nondormant econdary tumors. Nodal metastases were present in 5% of he patients at the time of their first presentation with prinary melanoma. Elective node dissections were performed n 6% of the men and 11% of the women. (10 refs)

8-4164 **Increased Risk of Brain Tumors in Children Exposed to Barbiturates.** (Eng) Gold, E. (Dept. pidemiology, Sch. Hygiene and Public Health, Johns Hopins Univ., Baltimore, MD, 21205); Gordis, L.; Tonascia, J.; zklo, M. *J Natl Cancer Inst* 61(4): 1031-1034; 1978.

patient-control study was conducted with children with rain tumors (BT) to investigate the possibility that the use f barbiturates, either prenatally by the mother or by the hild prior to his illness, might be associated with the development of BT in children. Interviews were conducted with 4 mothers of children with BT, and the results were comared with those obtained from 76 mothers of normal chilren and 12 mothers of children with other cancers. Mothers f children with BT more frequently reported using barbituates during their pregnancy with the index child than did nothers of normal children or mothers of children with other ancers. In addition, more children with BT were reported o have used barbiturates than normal children or children vith other malignant diseases, with most of the uses appearng to be unrelated to the symptoms resulting from the BT itself. The results suggest that barbiturates may play an etiologic role, and it is estimated that as many as 8% of BT in children may be attributable to the use of barbiturates either by the child or prenatally by the mother. (19 refs)

78-4165 **Cancer Mortality and Morbidity among Rubber Workers.** (Eng) Monson, R. R. (Dept. Epidemiology, Harvard Sch. Public Health, 677 Huntingdon Ave., Boston, MA, 02115); Fine, L. J. *J Natl Cancer Inst* 61(4): 1047-1053; 1978.

Mortality and morbidity from cancer were examined among a group of 13,570 white men who worked for at least 5 yr at an Akron, Ohio, rubber plant. The potential period of follow-up was from January 1, 1940, to June 30, 1976. Departmental work histories were based primarily on records maintained by the local union. The occurrence of cancer was measured by death certificates and by a survey of area hospital tumor registries from 1964 to 1974. Two analyses were made: (1) an external comparison of mortality rates among rubber workers vs rates among US white men, and (2) an internal comparison of morbidity rates among persons who were employed in various work areas of the plant. Excess cases of specific cancers (observed/expected numbers) among workers in specific work areas included: stomach and intestine: rubber making (30/14.4); lung: tire curing (31/14.1), fuel cells and/or deicers (46/29.1); bladder: chemical plant (6/2.4), tire building: (16/10.7); skin cancer: tire assembly (12/1.9); brain cancer: tire assembly (8/2.0); lymphatic cancer: tire building (8/3.2); and leukemia: calendering (8/2.2), tire curing (8/2.6), tire building (12/7.5), elevators (4/1.4), tubes (4/1.6), and rubber fabrics (4/1.1). Agents that may be responsible for these excesses include carbon blacks, softeners, extenders, plasticizers, antioxidants, and accelerators. Whether specific chemicals can be identified as having been directly responsible is problematic because of the complex nature of the work environment. (37 refs)

78-4166 **Further Analysis of Cancer Mortality Patterns among Workers Exposed to Cutting Oil Mists.** (Eng) Decoufle, P. (Environmental Epidemiology Branch, NCI, NIH, Bethesda, MD, 20014). *J Natl Cancer Inst* 61(4): 1025-1030; 1978.

Mortality patterns among two groups of oil mist-exposed workers at a heavy-industry machining plant were studied retrospectively, over a 30-yr period, to determine whether specific forms or sites of cancer occurred at greater than expected rates. The two groups comprised (1) 2,485 white men employed ≥5 yr in oil mist-exposed jobs between 1938 and 1967 and (2) a subgroup of 1,137 who spent at least 5 yr in jobs with heavy exposure to oil mist. The cause-specific mortality rates were compared to similar rates for the total US white male population. The total number of cancer deaths was very close to that expected. Analysis of mortality for each of 15 cancer sites showed no significant differences between observed and expected deaths for almost all comparisons. However, there was a twofold risk of cancer of the stomach and large intestine (combined) after 20 yr of follow-up in a subgroup of men with ≥5 yr exposure to cutting oil mists prior to 1938. Deaths from nonmalignant respiratory disease were significantly less than expected. It is concluded that exposure to mists of insoluble and soluble mineral oils in machining operations does not alter mortality for most cancer sites, including the respiratory system, but may affect the long-term occurrence of cancer of the stomach and large intestine. (32 refs)

78-4167 **Intestinal Metaplasia of the Stomach in Hawaii and Japan. A Study of Its Relation to Serum Pepsinogen I, Gastrin, and Parietal Cell Antibodies.** (Eng) Stemmermann, G. N. (Japan-Hawaii Cancer Study, 347 N. Kuakini St., Honolulu, HI, 96817); Ishidate, T.; Samloff, I. M.; Masuda, H.; Walsh, J. H.; Nomura, A.; Yamakawa, H.; Glober, G. *Am J Dig Dis* 23(9): 815-820; 1978.

The relation of serum pepsinogen I (PG I), fasting and postprandial gastrin, and antibodies against parietal cells to intestinal metaplasia (IMP) of the stomach was assessed in Hawaiian Caucasians (HC), Hawaiian Japanese (HJ), and indigenous Japanese (J), populations at low, intermediate, and high risk for gastric carcinoma, respectively. In addition, endoscopic mucosal biopsies were taken from parts of the stomach at minimal, max, and intermediate risk for IMP. PG I levels were low in 16.1% of the J, 9.3% of the HJ, but only 2.3% of the HC men, a finding consistent with stomach cancer risk. A low PG I level and IMP appeared to follow similar trends: each was more common among the J men, each appeared to be positively correlated with age, and each was more common in men than in women. A low PG I level was found to be highly specific for the presence of extensive IMP (162/169 patients with negative for <3 positive biopsies had normal levels) but only moderately sensitive for this condition (only 16/44 subjects with IMP at three sites had low PG I level). The absence of a low PG I level in the latter may be due to the fact that a significant portion of their oxyntic gland mucosa was not involved in the metaplasia. Neither abnormal serum gastrin levels nor the presence of parietal cell antibodies could be correlated with IMP. (19 refs)

78-4168 **Malignant Tumors in Relatives of Stomach Cancer Patients.** (Rus) Arion, A. I. (Dept. Epidemiology Malignant Tumors, Cancer Res. Center, Moscow, USSR). *Vopr Onkol* 24(7): 78-82; 1978.

The potential genetic predisposition to cancer of the stomach was studied in 223 stomach cancer patients and 3,831 relatives. Of the relatives, only 166 had any form of cancer (compared with expected incidence of cancer in the Russian population of 197.3). However, among first-degree relatives alone, the observed frequency of stomach cancer was significantly greater than the expected frequency in general population. In mothers, sisters, and daughters of female probands, stomach cancer frequency was 5.2 times the expected value. This increased frequency was not seen in male relatives of the female probands, but male and female relatives of male probands with stomach cancer were affected by the disease twice as frequently as control subjects. (14 refs)

78-4169 **Malignancies in German Thorotrast Patients and Estimated Tissue Dose.** (Eng) van Kaick, G. (Institut fur Nuklearmedizin, Deutschen Krebsforschungszentrums, Heidelberg, W. Germany); Lorenz, D.; Muth, H.; Kaul, A. *Health Phys* 35(1): 127-136; 1978.

Preliminary data on a follow-up study of 6,000 patients who had been subjected to Thorotrast (TT) examination and 6,000 controls are reported. Subjects from both groups (1,162 patients, 883 controls) who died prior to the beginning of the study (1968) were analyzed via their records. The av age at injection was 40 yr and the av time from injection to death was 17 yr. The av volume of TT injection was 30 ml. The following ratios compare the incidence of neoplastic diseases in the TT group to that in controls: liver cancer, 88/6; myeloproliferative diseases, 16/1; skeletal cancer, 2/0; lung cancer, 25/24; and spleen cancer 0/0. The absence of spleen tumors is surprising, because the radiation dose to the spleen was high (2,400 rads at 30 yr for 30 ml TT). To date, 802 of the living TT patients and 622 of the controls have been examined clinically and biophysically. The av age at injection was 28 yr and the av time from injection to first examination was 26 yr. The volume of TT (calculated from whole-body counting) was 22 ml. Since these examinations, 171 TT patients have died, 51 with liver tumors and 5 with leukemia. The av TT dose was about 17 ml in four of the leukemia patients, 33 ml in those who died with liver tumors. There were also three cases of reticulosarcoma. Including liver cirrhosis and leukemias, it is estimated that $>40\%$ of the patients with a known cause of death died from TT-related diseases. (12 refs)

78-4170 **Prevalence of Hepatitis B Virus Infection and Hepatocellular Carcinoma in Chinese-Americans.** (Eng) Szmuness, W. (Lab. Epidemiology, New York Blood Center, 310 E. 67th St., New York, NY, 10021); Stevens, C. E.; Ikram, H.; Much, M. I.; Harley, E. J.; Hollinger, B. *J Infect Dis* 137(6): 822-829; 1978.

The prevalence of hepatitis B virus (HBV) markers and excess mortality due to hepatocellular carcinoma (HCC) were studied in 666 Chinese permanently living in New York city. Approx 90% of the subjects were born outside the US, but 51% of the foreign-born subjects had lived in this country for at least 10 yr. Hepatitis B surface antigen (HBSAg) was detected in 9.3% of the subjects tested, antibody to this antigen (anti-HBs) in 57%, and antibody to the core antigen (anti-HBc) in 8.8%. These rates are 10-40 times higher than those found in other ethnic groups. Nearly all persons positive for HBsAg and anti-HBs were reactive to the subtypes prevalent in Asia; the e antigen was detected in only 3% of the HBsAg carriers. The incidence of anti-HBc alone or anti-HBs alone increased with age, but the incidence of HBsAg and of coexisting anti-HBs decreased with age. The age-standardized death rate from HCC among Chinese men, but not women, was 4 times higher than that among black men and 10 times higher than that among white men. An excess mortality was seen in Chinese of all ages. The findings that Chinese-Americans are at very high risk for both HBV infections and HCC support the hypothesis that these two conditions are causally associated. (24 refs)

78-4171 **Geographic Patterns of Bladder Cancer in the United States.** (Eng) Blot, W. J. (Environmental Epidemiology Branch, NCI, NIH, Bethesda, MD, 20014); Fraumeni, J. F. *J Natl Cancer Inst* 61(4): 1017-1023; 1978.

The geographic distribution of the 1950-1969 bladder cancer mortality rates (BCMR) in the US was correlated with demographic, socioeconomic, ethnic, and industrial data for the 3,056 US counties. Rates among whites and nonwhites of both sexes rose sharply with urbanization. For whites, male BCMR were not only high in urban areas, especially New Jersey, but also in rural New England, along the Illinois-Wisconsin border, in southern Michigan, and in southern Louisiana. A regional excess was most evident for white women in New England and northern New York. Increases in BCMR correlated with increasing population density, increasing socioeconomic standard, and a high percentage of British- and German-American residents. The largest industrial increases were seen in counties with chemical manufacturing operations, eg, 20/21 New Jersey counties. A positive correlation was also seen with the printing industry. Even after controlling for demographic variables, the Northeastern excess in BCMR among whites was sizable. For nonwhites, regional differences were small, but men showed a slight Southern excess and a positive urban gradient was obvious for both sexes. Male BCMR were considerably higher for whites than for nonwhites in the North but only marginally higher in the South. Female BCMR were greater for nonwhites than for whites across the country. During 1950-69, BCMR remained constant for white men and nonwhite women, increased slightly for nonwhite men, and decreased slightly for white women. (34 refs)

78-4172 **Lung Cancer Mortality and Urban Air Pollution.** (Eng) Weiss, W. (Dept. Medicine, Hahnemann Medical Coll., 6401 New College Building, 230 N. Broad St., Philadelphia, PA, 19102). *Am J Public Health* 68(8): 773-775; 1978.

The geographic variation of lung cancer mortality rates in Philadelphia was compared with the earliest obtainable information on the geographic variation in air pollution in this city. Study of lung cancer mortality in persons > 30 yr of age revealed that most cases occurred in white men; therefore, evaluation was confined to this segment. The areas of the city with high and intermediate rates of lung cancer mortality formed a broad band from the southern section into the near northeastern section along the eastern border of the city. These sections comprised a central business area with heavy automotive traffic and a high building density, low-income residential and commercial areas, and heavily industrialized areas. The sections with the lowest mortality rates were largely residential areas in the west, northwest, and far northeast sections of the city. Study of the concentrations of settled dust and the sulfation rate, based on pollution data obtained in 1960, revealed that the most heavily polluted areas had the highest lung cancer mortality rates a decade later. The highest rates for white women occurred in the most heavily industrialized sections. No data on smoking habits or occupational exposure were obtained, so interpretation of these results as a cause and effect relationship is unjustified. (7 refs.)

78-4173 **Lung Cancer after Employment in Shipyards During World War II.** (Eng) Blot, W. J. (Environmental Epidemiology Branch, Landow Bldg, Room 3C-07, NCI, Bethesda, MD, 20014); Harrington, J. M.; Toledo, A.; Hoover, R.; Heath, C. W.; Fraumeni, J. F. *N Engl J Med* 299(12): 620-624; 1978.

A case-control study was conducted to identify reasons for the exceptionally high rate of lung cancer diagnosed among male residents of coastal Georgia. The study group consisted of 458 lung cancer patients and 553 controls, most of whom were long-time residents of the area. Personal interview of the patients and controls, or next of kin in the event of death, covered place, type, and length of employment for all jobs held for 6 mo or more; duties performed and materials handled; and cigarette smoking habits. Estimates of relative risk of employment on lung cancer were calculated for 16 industrial categories. A significantly increased risk (1.6) was associated with employment in area shipyards during World War II. The excess risk increased sharply with smoking habits, indicating that there is strong synergism between these two risk factors. Assuming that 14% (the proportion among controls) of the general population had worked in shipyards and were at 1.6 times the usual risk of lung cancer, the coastal lung cancer rate would be expected to exceed the usual rate by 8%. Estimates of lung cancer mortality rates for 1970-1975 show that the rate in this area exceeds the national rate by 30%. This suggests that the coastal excess may be only partly attributable to wartime shipyard exposure. The failure to find a higher-than-av number of mesotheliomas, which occur even after relatively light exposures to asbestos, raises the possibility that hazards other than asbestos may also exist in the shipyards. (24 refs)

78-4174 **Computerized Retrieval of Case Histories.** (Ger) Crivelli, M. (Pneumologische Abteilung, Medizinische Universitatsklinik, Inselspital, CH-3010 Bern, Switzerland); Zeller, C.; Scherrer, M. *Schweiz Med Wochenschr* 108(27): 1026-1031; 1978.

The efficiency of the STAIRS-IBM computer program for the retrieval of case histories stored in text form was tested with the use of chronic bronchitis in lung cancer patients as an example. Computer selection was compared with manual selection, which involved reading all 473 case histories stored from 1974 to 1977. According to manual selection, which took 3 mo, 219/473 lung cancer patients had a history of chronic bronchitis of > 5 yr duration, and only 180 had no history of preexisting chronic bronchitis. The computer correctly selected 87% of the former group and 74% of the latter within 4 hr. With further modifications in the program, the accuracy of selection reached 90%. (10 refs)

78-4175 **Population Distribution of Histological Types of Lung Cancer. Epidemiologic Aspects in Israel and Review of the Literature.** (Eng) Modan, B. (Dept. Clinical Epidemiology, Chaim Sheba Medical Center, Tel-Hashomer, Israel). *Isr J Med Sci* 14(7): 771-784; 1978.

A nationwide study of lung cancer in Israel during 1968-1970 demonstrated a low to moderate incidence in men and a high incidence in women, compared with other countries. The sex ratio was relatively lower than expected. This discrepancy results from a proportionately lower rate of squamous cell carcinoma in men compared with the rates found in most other reports and a higher rate of adenocarcinoma in women, and it is consistent with similar trends in North American Jews from New York, Pittsburgh, and Montreal. Literature related to the relative frequencies of various histological subcategories of lung cancer is reviewed, and the etiologic and prognostic importance of a separate assessment of each distinct cell type entity is emphasized. (52 refs)

78-4176 **Primary Lung Cancer and Asthma.** (Eng) Ford, R. M. (Div. Allergy, Royal Adelaide Hosp., Adelaide, S. Australia). *Ann Allergy* 40(4): 240-242; 1978.

A total of 6,021 persons ≥ 40 yr of age who were chronic asthma suffers (> 5 yr duration) were followed over a 20-yr period to determine the incidence of lung cancer. Only two (0.032%) developed lung cancer, compared with 0.314% in the general population. The two were a 40-yr-old woman who had smoked an av of 20-25 cigarettes a day for 25 yr and a 55-yr-old man who had averaged 30-35 cigarettes a day f
20 yr. Analysis of the smoking habits of the asthmatics i
dicated that only 16.9% had smoked over any significa
period during the previous 5 yr, compared with 40% of t
general population. Further investigations indicated that
those who did smoke, they did so to a lesser degree th
persons in the general population. About 15% of the asthr
patients had received long-term immunosuppressive thera
with corticosteroids and/or hyposensitization therapy
some time during the 20-yr period. Enhanced immunologi
activity in the asthmatics could be a factor in reducing th
cancer incidence. (23 refs)

78-4177 **Probabilities of Eventually Developing and
Dying of Cancer (Risk Among Persons Pre
ously Undiagnosed with the Cancer).** (Eng) Seidman,
(Dept. Epidemiology and Statistics, American Cancer Soc
ty, New York, NY); Silverberg, E.; Bodden, A. *Ca* 28(
33-46; 1978.

A new method for computing the probabilities (P) of develo
ing and dying of cancer among persons not previously dia
nosed with that cancer is described, and the resulting da
are tabulated. The P are based on the age-, race-, a
sex-specific incidence rates/100,000 found in National Ca
cer Institute studies conducted in 1947 and in 1969-1971,
conjunction with 1949-1951 US life tables and mortality da
Nonmelanoma skin cancer is not included. The P of eventu
ly developing cancer, including carcinoma in situ (CIS),
increasing in all race-sex groups, the chances in 1970 bei
> 1/4 in whites and close to 1/4 in nonwhites. This is a
true for invasive cancer (IC) alone except in white wome
in whom the decline in IC incidence has been great enou
to balance the added number of cases resulting from increa
in life expectancy. Whether or not CIS is included, wh
women still showed the highest 1970 P for all forms of canc
27% for IC and 30% for IC + CIS. In men, the P of develo
ing lung and prostate cancer have increased substantial
The sharpest increases for all cancers occurred in nonwh
men, from 15% in 1950 to 23% in 1970. The chances at bi
of eventually dying of cancer are increasing, and in 1970 th
were > 1/7. The eventual P for men exceeded those for wo
en, reversing the situation observed in 1950. Lung canc
accounted for a large part of this increase. For white wome
the increase was not due to any increase in cancer death ra
but to a decrease in other causes of death. In 1970, the P
dying of cancer were 17% for white men, 16% for wh
women, 15% for nonwhite men, and 13% for nonwhite wo
en. (18 refs)

78-4178 **Frequency of Tonsillectomy in Bronchial Ca
cer Patients.** (Ger) Jentgens, H. (HNO-Klin
Koln, W. Germany); Matzker, J.; Steinhaus, C. *Laryn
Rhinol Otol (Stuttg)* 57(3): 190-193; 1978.

Relationships between bronchial cancer and tonsillectomy were studied in 1,415 bronchial cancer patients an 1,415 matched normal controls. The cancer patients included 1,289 men and 126 women aged 30-79 yr. Only 7.5% were nonsmokers; 80% smoked 10-50 cigarettes/day, and 12.5% smoked a pipe or cigars. Squamous epithelial carcinoma was found in 777 patients. The incidence of tonsillectomy was 84/1,415 among the cancer patients and 265/1,415 among the controls. The findings, which agree with previous findings concerning the incidences of tonsillectomy in children and adults with leukemia and ear-nose-throat tumors, suggest a causal relationship between the presence of the tonsils and malignant tumors. (4 refs)

78-4179 **Relationship Between Respiratory Cancer and Wetlands Residency in Louisiana.** (Eng) Voors, A. W. (Dept. Preventive Medicine, Louisiana State Univ. Medical Center, 1542 Tulane Ave., New Orleans, LA, 70112); Johnson, W. D.; Steele, S. H.; Rothschild, H. *Arch Environ Health* 33(3): 124-129; 1978.

A possible association between respiratory cancer and residence in the wetlands of southern Louisiana was assessed with the use of two other environmental factors known to influence respiratory cancer mortality, smoking and residence in urban communities. There was an association between wetlands residency and mortality due to tracheal, bronchial, and lung cancers among white and black men, but not among women. A smaller but significant association was also found for wetlands residency and other smoking-related cancers among men and black women. The rates for cancer of the trachea, bronchus, and lung among wetlands men were higher than the national av. Since the observed association between respiratory cancer mortality and residence in the wetlands was confined to men, and since the men smoked more than women, the existence of a wetlands-associated substance promoting respiratory cancer in smokers is suggested. (31 refs)

78-4180 **Patterns of Laryngeal Cancer in the United States (Letter to Editor).** (Eng) Blot, W. J. (Environmental Epidemiology Branch, NCI, Bethesda, MD, 20014); Fraumeni, J. F.; Morris, L. E. *Lancet* 2(8091): 674-675; 1978.

Examination of factors that may be responsible for the geographic distribution of laryngeal cancer in the US, where rates during 1950-1969 increased sharply with urbanization, suggests that not only alcohol consumption but also tobacco smoking and occupational exposures are involved. (10 refs)

78-4181 **Occupational and Nonoccupational Factors Involved in Laryngeal Cancer.** (Ger) Wolf, O. (Hals-Nasen-Ohren-Klinik, Bezirkskrankenhaus, Auenweg 38, DDR-4502 Dessau-Alten, E. Germany). *Z Gesamte Hyg* 24(3): 174-177; 1978.

Comparison of the incidence of laryngeal cancer among residents of three neighboring districts and among individuals employed in the wood and chemical industries revealed a significant increase in the risk of this disease among the latter. Occupational and nonoccupational factors involved in the development of laryngeal cancer are discussed. Occupational exposure to harmful substances via inhalation, tobacco smoke inhalation, and chronic disease of the upper respiratory tract are important contributing factors. (20 refs)

78-4182 **Malignancies in Danish Thorotrast Patients.** (Eng) Faber, M. (Finsen Lab., Strandboulevard 49, Copenhagen, Denmark). *Health Phys* 35(1): 153-158; 1978.

Results of a Thorotrast (TT) follow-up study conducted in Denmark since 1949 are reported. As of 1973, 1,012 exposed subjects had been identified (injected between 1935 and 1946, 391 of whom were still living. Of the 95 cancers and leukemias detected in this population, 43 were considered to have been induced by TT: 11 hemangioendotheliomas, 9 cholangiocarcinomas, 12 hepatomas, and 11 leukemias. The three types of liver tumors had a similar incidence, latency period (minimum of 17 yr), rise in cumulative incidence with time, and radiation dose to the liver. The minimum latency period for the leukemias was 8 yr; no cases of leukemia appeared >23 yr after the injection. No bone tumors were observed. Four of the 11 cases of respiratory cancer (all men) had latency periods <15 yr, which does not support a radiation induction. However, the high ratio of anaplastic lung tumors/epidermoid lung tumors (5/2) agrees with findings in uranium miners. It is uncertain whether the two cases of pleural mesothelioma in TT patients may have been induced by TT, because there is no evidence for significant irradiation of the pleura. It is concluded that liver cancers and leukemias can be induced by TT, but a larger population or a longer follow-up time is needed to determine whether bone sarcomas and lung tumors are induced by iv-injected TT. (12 refs)

78-4183 **Current Status of the Study of ^{226}Ra and ^{228}Ra in Humans at the Center for Human Radiobiology.** (Eng) Rowland, R. E. (Center Human Radiobiology, Argonne Natl. Lab., Argonne, IL, 60439); Stehney, A. F.; Brues, A. M.; Littman, M. S.; Keane, A. T.; Patten, B. C.; Shanahan, M. M. *Health Phys* 35(1): 159-166; 1978.

Populations being examined in a large national study of radium effects in humans and malignancies recorded to date are reported. Of 3,803 known individuals with documented exposure to Ra, 2,828 were exposed through the dial-painting industry, in which luminous Ra paints are used; 492 through laboratory work; 383 through medical usage; and 100 through miscellaneous routes. As of April 1974, complete studies had been made of 1,572 individuals. An additional 1,163 individuals (589 living, 574 dead) have been identified but not yet studied, and 1,068 have not been located. As the hazards of Ra became known, the dial-painting industry adopted control measures that were so effective, no dial painters have been found with a cumulative skeletal dose > 1,000 rads who started painting after 1926. However, the individual habits of each employee determined their actual intake of Ra, because the length of employment did not correlate with Ra intake. Two general types of malignancies in this population were considered radiation-induced: malignant bone tumors (54 cases) and carcinomas of the mastoids and paranasal sinuses (26 cases). The lowest radiation dose to a person who subsequently developed a bone tumor was 888 rads; the lowest does at which a carcinoma of the mastoids or paranasal sinuses was diagnosed was 605 rads. (13 refs)

78-4184 **Chemical Studies on Tobacco Smoke. LIX. Analysis of Volatile Nitrosamines in Tobacco Smoke and Polluted Indoor Environments.** (Eng) Brunnenmann, K. D. (Div. Environmental Carcinogenesis, Naylor Dana Inst. Disease Prevention, American Health Foundation, Valhalla, NY); Hoffmann, D. *IARC Sci Publ* (19): 343-356; 1978.

The possible contribution of N-nitrosamines (NA's) from tobacco mainstream and sidestream smoke to the contamination of indoor atmospheres was investigated. Chemical analysis indicated that the mainstream smoke from cigarettes and cigars contains trace amounts of the volatile NA's N-nitrosodimethylamine [5.7-6.5 nanograms/cigarette (ng/cig)], N-nitrosoethylmethylamine (0.4-7.7 ng/cig), N-nitrosodiethylamine (1.1-3.8 ng/cig), and N-nitrosopyrrolidine (5.1-34 ng/cig). The volatile NA's in sidestream smoke exceeded those in mainstream smoke by 10-50 times. Air was sampled in bar cars of trains, a local bar, a jai-a-lai arena, and other indoor areas polluted by tobacco smoke. The results showed that during 1 hr in a smoke-polluted indoor environment, a nonsmoker may inhale volatile NA's in quantities equal to those in the mainstream of 0.5-30 cigarettes. It has yet to be determined whether volatile NA's play a role in cancer induction in tobacco-related cancer sites. They do not appear to be contact carcinogens, even in animals. It also has yet to be determined whether they play a role at those cancer sites where they are actively metabolized; eg, the esophagus, kidney, bladder, and pancreas. (9 refs)

78-4185 **Analytical Determination of N-Nitroso Compounds in Pesticides by the United States Environmental Protection Agency--A Preliminary Study.** (Eng) Cohen, S. Z. (Environmental Protection Agency, Washington, DC); Zweig, G.; Law, M.; Wright, D.; Bontoyan, W. R. *In: Environmental Aspects of N-Nitroso Compounds. Proceedings of a Working Conference Held at the New England Center for Continuing Education, University of New Hampshire Durham, 22-24 August 1977.* International Agency for Research on Cancer. (Lyon, France): Vol. 19, pp. 333-342; 1978

Preliminary results from an analytical survey of 70-80 pesticides for N-nitroso compounds are presented. Representativ pesticides were selected on the basis of three routes of potential N-nitroso contamination: (1) industrial process formatio and carryover; (2) in situ (container) nitrosation, and (3) us of contaminated amines in the manufacturing process. Duplicate samples were analyzed by two different laboratories using gas chromatography and high-pressure liquid chromatography interfaced with Hall, UV, and chemiluminescen (thermal energy analyzer) detectors. The analysis has bee directed toward the detection of six compounds: N-nitrosodimethylamine (NDMA), N-nitrosodiethanolamine N-nitrosodipropylamine, N-nitrosobutylethylamine, N-nitrosobutralin, and N-nitrosoatrazine (NAT). Eight of 25 pesticides analyzed contained nitrosamines, 4 of which wer dinitroaniline-type compounds. Fourteen samples wer amine salts; two of these contained nitrosamines at or abov the 1-ppm limit of sensitivity of the tests. Both samples o dimethylamine showed > 25 ppm NDMA. No NAT was detected in the atrazine products. Based partly on these results the Environmental Protection Agency has decided to conduct risk-benefit analyses of pesticides suspected of containing N-nitroso contaminants, with special consideration to b given to oncogenic and mutagenic potential. (16 refs)

78-4186 **Recent Studies in Canada on the Analysis an Occurrence of Volatile and Non-volatile N-Nitroso Compounds in Foods.** (Eng) Sen, N. P. (Food Res. Div. Health Protection Branch, Ottawa, Canada); Donaldson, B A.; Seaman, S.; Iyengar, J. R.; Miles, W. F. *IARC Sci Pub* (19): 373-393; 1978.

Research devoted to the monitoring of N-nitroso compound in foods and to the development of new analytical technique for this purpose is reviewed. Analysis of 62 cheese samples using methods similar to those used for meat, indicated tha traces of nitrosamines (2-20 μg/kg), specifically N-nitrosodimethylamine, N-nitrosodiethylamine, and N-nitrosopiperidine, can occur in cheese. Nitrosamines were detected in samples prepared without the addition of nitrate making it difficult to determine whether there is any relatio between the addition of nitrate and the occurrence of nitrosamines in cheeses. Several new analytical methods were developed for the determination of nonvolatile nitroso compound such as nitrosohydroxypyrrolidine, nitrosodiethanolamine nitrosoproline (NPRO), nitrosohydroxyproline (NHPRO) and nitrosoglyphosate (a nitrosated herbicide). All of thes compounds can be converted to volatile derivatives and the analyzed by gas-liquid chromatography-mass spectrometr (GLC-MS) or by conventional GLC using a specific detector Very low levels (22-44 μg/kg) of NPRO were detected in si samples of raw bacon analyzed by GLC-MS. None of these samples contained any detectable level of NHPRO. (35 refs)

78-4187 **The Influence of Membrane Lipids on the Proliferation of Transformed and Untransformed Cell Lines.** (Eng) Hatten, M. E. (Dept. Neuropathology, Harvard Medical Sch., Boston, MA, 02115); Horwitz, A. F.; Burger, M. M. *Exp Cell Res* 107(1): 31-34; 1977.

A cell cycle analysis of untransformed 3T3 cells and transformed SV101-3T3 cells grown in a medium depleted of lipid and biotin revealed that 3T3 cells accumulate in G1, whereas SV101-3T3 cells do not. The addition of insulin to the arrested 3T3 cells triggered their escape from G1 only when biotin or fatty acids were present. The proliferation of 3T3 and SV101-3T3 cells was markedly inhibited when the cells were grown in Dulbecco's modified Eagle's medium (DMEM) supplemented with a lipid-depleted calf serum. This inhibition was reversed for both cell types by addition of the lipid extracted from the serum, the exogenous lipid (as free fatty acid or esterified to the phospholipids), or biotin. The reversal depended quantitatively on the lipid supplement and the cell line. For example, both the growth rate and density saturation of 3T3 cells grown in DMEM with biotin or oleate were markedly less than those of 3T3 cells grown in DMEM supplemented with regular calf serum. Of the fatty acids tested, only a mixture of those initially present in the serum (palmitate, stearate, oleate, and linoleate) restored growth to densities approaching those of cells grown in DMEM supplemented with regular calf serum. The proliferation of SV101-3T3 cells in lipid-depleted medium (LDM) supplemented with biotin or fatty acid differed from that of 3T3 cells in three ways: (1) the proliferation of SV101-3T3 cells grown in LDM supplemented with biotin or oleate was nearly identical with that of cells grown in media supplemented with regular calf serum or reconstituted serum; (2) SV101-3T3 cells grown in LDM supplemented with reconstituted serum had their growth restored to densities similar to those of the same cells grown in DMEM with regular calf serum; (3) SV101-3T3 cells appeared to be more sensitive to the toxic effects of saturated fatty acids. Relatively low densities and a lack of proliferative response with SV101-3T3 cells enriched with elaidate leads to the speculation that the physical properties of the cell membrane were altered so that proliferative signals were not transmitted and/or received. MISCELLANEOUS

78-4188 **Experimental Studies on Factors Affecting Tumor Growth in the Liver. I. A Scrutiny of Number of Cells and Volume of Fluid Inoculated.** (Eng) Kawaguchi, T. (Second Dept. Pathology, Fukushima Medical Coll., Fukushima, Japan); Ikeda, K. *Fukushima J Med Sci* 23(1/2): 11-16; 1976.

The effects of the intrahepatic injection of various numbers of AH 130 rat ascites hepatoma cells in various volumes of tumor cell suspension were studied in female Donryu rats. Injection of 2 x 10^7, 10^6, 10^5, 10^4, 10^3, and 10^2 cells resulted in tumor growth within 90 days in 100%, 100%, 87%, 57%, 37%, and 20%, respectively, of the treated rats. Tumor growth was not influenced by the volume of the tumor cell suspension except when 2 x 10^2 cells were injected; in this case, the tumor incidence increased with increasing volume. The larger the number of tumor cells injected, the more steeply the survival curves fell. In 95% of the animals, tumor growth occurred at the site of injection in the liver. Direct invasion into the peritoneum and metastasis to the lungs, kidneys, etc, were caused by the tumor node established at the injection site. The intrahepatic injection of tumor cells provides a satisfactory experimental method for studying factors related to the growth of tumors in the liver. (7 refs)

78-4189 **Neoplasms Produced from C3H/10T 1/2 Cells Attached to Plastic Plates; Saturation Density, Anchorage Dependence and Serum Requirement of In Vitro Lines Correlated with Growth Aggressiveness In Vivo.** (Eng) Paranjpe, M. S. (NCI, NIH, Bethesda, MD, 20014); Eaton, S. A.; Boone, C. W. *J Cell Physiol* 96(1): 63-72; 1978.

A number of in vitro lines established from C3H/10T 1/2 tumors wereexamined to determine if they showed one or more of the phenotypic alterations usually associated with transformation in vitro. Polycarbonate plates (1 x 5 x 10 mm) planted with 3 x 10^4 C3H/10T 1/2 cells were implanted sc into male C3H mice. Ten of 27 mice developed tumors at the site of implantation within 11-14 wk. (This cell line is nontumorigenic when inoculated sc in saline suspension.) Spontaneous neoplastic transformation occurred in vivo as a single-stage process of positive selection for cellular alterations directly associated with neoplastic behavior. Early passages of cell lines from four different C3H/10T 1/2 tumors explanted back in culture were quantitatively examined for tumorigenicity and for alteration in the properties of density inhibition, anchorage dependence, serum requirement, and plasminogen activator production. A consistent quantitative relationship was found between the degree of growth aggressiveness in vivo and the degree of expression of these phenotypic markers of the transformed state in vitro during early passages of the cell lines after tumor explantation. (21 refs)

78-4190 **Establishment of Cultured Cell Lines Derive from a Human Gastric Carcinoma.** (En Sekiguchi, M. (Dept. Clinical Oncology, Inst. Medic Science, Univ. Tokyo, Shirokanedai, Minato-ku, Tokyo 10 Japan); Sakakibara, K.; Fujii, G. *Jpn J Exp Med* 48(1): 61-6 1978.

A human gastric carcinoma cell line, KATO-II, and a s bline, KATO-III, were established in vitro from a pleur effusion of a 55-yr-old male patient. KATO-II cells were e tablished with the use of human cord serum, and they ha been successfully subcultured >129 times for >3 y KATO-III cells have been cultured in medium containi 20% fetal bovine serum, and they have been serially passag >176 times. Both cell lines are morphologically simil They are round and free floating and they have the cytolog cal features of signet ring cells. Population doubling times f KATO-II and KATO-III cells were 74 and 36 hr, respectiv ly. The modal chromosome numbers of these lines fell in t tetraploid range. KATO-III cells exhibited little alkali phosphatase activity. Pepsinogen contents of both cell lin were almost negligible. Both cell lines formed tumors in an thymocyte serum-treated hamsters at an inoculum size of 1 cells. The microscopic appearance of the resultant tumo was consistent with poorly differentiated adenocarcinom comparable to the original tumor. (22 refs)

78-4191 **Growth of Embryonal Carcinoma Cells Serum-free Medium.** (Eng) Rizzino, A. (De Biology, Univ. California at San Diego, La Jolla, CA, 9209 Sato, G. *Proc Natl Acad Sci USA* 75(4): 1844-1848; 1978

Two mouse embryonal carcinoma cell lines, PCC.4 aza-1 a F_9, were grown for extended periods of time in serum-f F-12 medium supplemented with Pedersen fetuin, insul transferrin, and 2-mercaptoethanol (EM-1 medium). Wh the cells were transferred from medium containing serum this serum-free medium, growth continued without any c tectable lag. However, the morphology of both PCC.4 az and F_9 cells differed somewhat from cells grown in mediu containing serum. The cells were smaller and they did r grow in close association with one another. PCC.4 aza-1 ce grown in this serum-free medium for >20 generations tained their capacity to differentiate in vivo. When nude m were inoculated with PCC.4 aza-1 cells grown in serum-f or serum-containing medium, tumors were formed withi wk in all mice, and the tumors were histologically simil It is concluded that EM-1 medium can be used for t long-term growth of embryonal carcinoma cells. (22 refs

78-4192 **Rate of Cell Division in Atypias and Invasi Carcinoma of the Uterine Cervix of the Mous** (Eng) Rubio, C. A. (Inst. Pathology, Karolinska Sjukhus

Karolinska Inst., 104 01 Stockholm 60, Sweden). *J Natl Cancer Inst* 61(1): 259-263; 1978.

The rate of cell division during a 6-hr period was determined in cervical epithelia from 64 normal C57BL mice, 26 mice with cervical atypias, and 8 mice with invasive carcinoma. Cervical atypias and carcinomas were induced by intravaginal application of 1% benzo(a)pyrene (BP) in acetone 2x/wk for 5 mo. Mitosis was arrested with colchicine. The ratio of dividing basal cells to total dividing cells and the basal cell division rates for the 6-hr period were both significantly greater in normal epithelia than in atypias and greater in atypias than in invasive carcinomas. The differences were not estrous cycle-dependent. Normal epithelia, epithelia with atypia, and invasive carcinomas all showed areas rich in mitotic figures alternating with areas showing no mitoses. These findings support the view that the proliferation of squamous cells in cervical tumors is lower than that in the tissue of origin, and they militate against the hypothesis that the invasion of the host is conveyed by an increased number of mitotic figures in the atypical epithelia. The occurrence of areas with mitotic activity suggests the existence of focally distributed and probably alternating, synchronous cell production in normal cervical epithelium, a process that apparently was not altered by topical BP application or by carcinogenesis. (20 refs)

78-4193 **The Malignant Transformation: The Nature of Its Effects on Cell Replication Characteristics.** (Eng) Gilbert, D. A. (Natl. Inst. Virology, Private Bag X4, Sandringham 2131, S. Africa). *S Afr Med J* 74(2): 48-49; 1978.

An earlier concept of the mechanism of malignant transformation has been extended to cover graded responses in cell behavior. It is now suggested that malignant transformation alters the probability of replication as a result of intracellular changes and that this occurs through an increase in the sensitivity of the cell cycle switch. When the intracellular regulators of replication overcome the sensitivity of the cell cycle switch, replication occurs. If the latter is lowered by malignant transformation, the cell can replicate at a higher frequency than normal cells; yet, under suitable conditions, the rates of continuous replication may be similar. Evidence has suggested that replication in vivo is regulated by the combined action of several interacting regulators, although one or the other may dominate in a particular case. A change in sensitivity toward the dominant agent as a result of transformation may thus make the cell more responsive to the other regulators. Therefore, tumor growth could be manipulated by levels of physiological agents other than that responsible for preventing proliferation in the tumor tissue. The concept provides an explanation for the ability of cancer cells to replicate more frequently than normal cells in vivo without requiring that they exhibit marked distinctions in behavior in vitro and for the ability of a tissue to yield tumors with a spectrum of growth rates (ie, the Morris hepatomas). (21 refs)

78-4194 **Motility of Leukemia Cells.** (Eng) Haemmerli, G. (Div. Cancer Res., Inst. Pathology, Univ. Zurich, Zurich, Switzerland); Strauli, P.; Felix, H. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 481-482; 1978.

The motility of human and rat leukemia cells was studied by time-lapse cinematography and scanning electron microscopy. With rat leukemias, the unclassifiable leukemia L5222 was highly locomotive and the myeloid leukemia BN ML was essentially nonlocomotive. Motility of human leukemias was independent of their myeloid, lymphoid, or unclassified origin, and a given cell type could display a wide range of motility. Motility is a key factor in modeling the shape and surface morphology of cells. (6 refs)

78-4195 **Studies on the Nature of Protease-induced Growth Stimulation in Normal and Transformed BHK Cells.** (Eng) Kiehn, D. (Dept. Microbiology and Immunology, Univ. Washington, Seattle, WA, 98195); Brown, M. *J Cell Physiol* 97(2): 169-176; 1978.

Studies of the nature of the protease-induced growth response(s) in normal and transformed baby hamster kidney (BHK) cells and of the molecular characteristics of trypsin that are involved in mitogenic activity are reported. In the presence of growth-limiting serum concentrations, trypsin displayed mitogenic activity on actively growing but not quiescent BHK cells. These results suggest that BHK cells arrested in G_1 (G_0) are not sensitive to protease-induced growth stimulation. Studies of denatured trypsin fragments indicated that at least some of trypsin did not require the conformation and size of the native enzyme. Cellular multiplication induced by the addition of fresh serum to quiescent BHK cultures was not inhibited by high concentrations of soybean trypsin inhibitor. Similar to previous findings it was observed that plasmin was not sufficient to initiate the growth of BHK cells in soft agar. Trypsin also failed to enhance the growth of a thermosensitive polyoma-transformed BHK line in soft agar at the restrictive temperature. Finally, the growth of transformed BHK cells in soft agar did not display a requirement for plasminogen and was not inhibited by soybean trypsin inhibitor. These studies argue against the involvement of plasmin or other exogenous trypsinlike enzymes in the growth and transformation of BHK cells. (23 refs)

78-4196 **Trichomonal Granuloma of the Pelvic Cavity in a Rhesus Monkey.** (Eng) Migaki, G. (Registry Comparative Pathology, Armed Forces Inst. Pathology, Washington, DC, 20306); Benirschke, K.; McKee, A. E.; Casey, H. W. *Vet Pathol* 15(5): 679-681; 1978.

In a study of the effects of diethylstilbestrol (DES) on gestational length, a normal Rhesus monkey underwent laparotomy before her normal parturition date and DES was injected im into the fetus. After a normal parturition, she became moribund and was killed 72 days postpartum. Autopsy revealed a trichomonal granuloma behind the uterus and attached to the sigmoid colon. It is suggested that the infection took place during laparotomy; the trichomonad species was not identified. (8 refs.)

78-4197 **Nutrition and Hormone Levels in Relation to Breast Cancer and Coronary Heart Disease.** (Eng) Hill, P. (Naylor Dana Inst. Disease Prevention, American Health Foundation, Dana Road, Valhalla, NY, 10595); Wynder, E. L.; Helman, P. *Clin Oncol* 4(1): 34-45; 1978.

The hormone profiles and serum lipid levels of healthy pre- and postmenopausal Bantu and Japanese women (B and J; low risk of breast cancer) were investigated and compared with values found in Caucasian women (C; high risk of breast cancer). The cholesterol levels were lower in premenopausal B vs J or C women, but the estrogen levels were significantly higher in B and J women vs C women. Cholesterol levels were higher in postmenopausal C women than in the other two groups, but the estrogen levels were comparable. In C women with premature castration or late pregnancy, marked differences in estrogen levels among the groups was evident; the cholesterol content was only increased in the late pregnancy group. The results indicate that the hormone profiles in B and J women are different from those in C women and that the serum lipid levels in Caucasians are higher after puberty. No correlation was evident between the cholesterol and estrogen levels in C women at different risk for breast cancer. The difference between the races may be partly associated with dietary habits. (58 refs)

78-4198 **Correlation Between Characteristics of Transformation and Malignancy of Intra and Interspecific Somatic Hybrid Cells.** (Eng) Foa, C. (Unite 119 I.N.-S.E.R.M., 27, Boulevard Lei Roure, 13009 Marseille, France); Simonetti, J.; Berebbi, M.; Fischer, P.; Vetterlein, M. *Oncology* 35(2): 58-62; 1978.

The transformed properties of five hybrid cell lines that had either one or another parent in common were studied and compared with the tumorigenicity of the lines. Hybrids were formed from human, Chinese hamster, and mouse cell lines. Three hybrid cell lines derived from the Chinese hamster DC-3F/ADX/Aza line were resistant to actinomycin D. This property appeared to be correlated with the presence of a marker chromosome from the common parent. The tumorigenicity in cortisone-treated Syrian hamsters was intermediate between those of the parental lines. Agglutinability by concanavalin A, however, was variable. Three hybrid cell lines derived from strain A9 or clone 1D, both derived from mouse fibroblasts, showed similar transformation characteristics, but two were tumorigenic and one was not. It i
concluded that the properties of the common parent are ofte
expressed in hybrids, but that properties not found in eithe
parent are sometimes found in the hybrid line as a result o
complementation. It is also concluded that somatic cell hybridization is a useful tool in the analysis of cell transformation, but it is limited by the wide variation in the karyologica
evolution of hybrid cell lines. (27 refs)

78-4199 **Differential Response of Cultured Mouse Mammary Cells of Varying Tumorigenicity to Cytochalasin B'.** (Eng) Steiner, M. R. (Dept. Virology, Baylo
Coll. Medicine, Houston, TX, 77030); Altenburg, B.; Richards, C. S.; Dudley, J. P.; Medina, D.; Butel, J. S. *Cancer Re*
38(9): 2719-2721; 1978.

Cultured BALB/c mouse mammary gland epithelial cells o
varying oncogenic potential in vivo were examined for thei
ability to multinucleate in the presence of cytochalasin I
(CB). Highly tumorigenic cell lines derived from mammar
tumors with hormonal, viral, or chemical carcinogen etiologies were extensively multinucleated when cultured i
CB-supplemented medium. Normal mammary gland cell
from either pregnant or lactating animals were predominantly mono- or binucleate under comparable conditions. At lov
passage levels after cloning, cell lines derived from a chemica
carcinogen-induced mammary tumor were weakly oncogeni
and remained largely mono- or binucleated when cultured i
CB-supplemented medium. At higher cell passage level
both the ability to produce tumors in vivo and the degree o
multinucleation in CB-supplemented medium increase
dramatically with the clonal cell lines. Thus, the response o
cultured mouse mammary gland epithelial cells to CB in vitr
may be useful as a marker of the oncogenic potential of thes
cells. (18 refs)

78-4200 **Mutagenesis During In Vitro DNA Synthesis**
(Eng) Weymouth, L. A. (Dept. Biology, Massachusetts Inst. Technology, Cambridge, MA, 02139); Loeb
L. A. *Proc Natl Acad Sci USA* 75(4): 1924-1928; 1978.

The error frequency of in vitro DNA synthesis using a natural DNA template was measured with a biological assay fo
nucleotide substitutions. φX174 bacteriophage DNA containing an amber mutation (*am3* locus) was copied in vitro
by *Escherichia coli* DNA polymerase I, and the reversion
frequency of the progeny DNA was determined by transfection of *E. coli* spheroplasts. *E. coli* polymerase I made les
than one mistake at the *am3* locus for every 7,700 nucleotide
incorporated under standard reaction conditions. Substitution of Mn^{2+} for Mg^{2+} and unequal concentrations of deoxynucleoside triphosphate substrates raised the mutation to >
1/1,000. This method makes it possible to measure the mutation rate of natural DNA synthesis in a biochemically define
in vitro system. (29 refs)

Subject Index:

Abnormalities
- Benzene
  - Maternal-Fetal Exchange, 78-3776
  - Skeleton, Rat, 78-3776
- Estradiol
  - Cervicovaginal Epithelium, Mouse, 78-3797
- Ethylene, Chloro-
  - Maternal-Fetal Exchange, 78-3813
  - Teratogenic Effect, Rat, 78-3815
- Radiation, Ionizing
  - Pregnancy, Review, 78-3659
- Toluene
  - Maternal-Fetal Exchange, 78-3776
  - Skeleton, Rat, 78-3776
- Trypan Blue
  - Central Nervous System, 78-3813
  - Maternal-Fetal Exchange, 78-3813
- Xylene
  - Maternal-Fetal Exchange, 78-3776
  - Skeleton, Rat, 78-3776

Acetaldehyde
- Diethylamine, *N*-Nitroso-
  - Microsomes, Liver, 78-3878
- Dimethylamine, *N*-Nitroso-
  - Microsomes, Liver, 78-3878
- Ethylamine, *N*-Methyl-*N*-nitroso-
  - Microsomes, Liver, 78-3878
- Smoke Condensate
  - Quantitation Method, 78-3698

Acetamide, *N*-(Acetyloxy)-*N*-fluoren-2-yl-
- Chromatids
  - Ovary Cells, Hamster, 78-3700
- DNA, Binding
  - Thioguanine Resistance, 78-3699
- DNA Repair
  - Cells, Cultured, 78-3854
- Endonucleases
  - Cleavage Sites, 78-3724
- Fibroblasts
  - Thioguanine Resistance, 78-3699
- Hypoxanthine Phosphoribosyltransferase
  - Mutagenic Activity, 78-3699
- Xeroderma Pigmentosum
  - DNA Repair, 78-3848, 78-3914

Acetamide, *N,N*-Dimethyl-
- Ames Test
  - Mutagenic Activity, 78-3825

Acetamide, *N*-Fluoren-2-yl-
- Albumins
  - Liver, Rat, 78-3705
- Alpha Fetoproteins
  - Liver, Rat, 78-3705
- Ames Test
  - Carcinogenic Potential, 78-3707
  - Mutagenic Activity, 78-3701
  - S-9 Fraction, Cotton Rat Liver, 78-3707
- Bladder Neoplasms
  - Alkaline Phosphatase, 78-3704
  - Carcinoma, Papillary, 78-3704
  - Carcinoma, Transitional Cell, 78-3704
  - Foreign Bodies, 78-3703
  - Hyperplasia, 78-3704

Acetamide, *N*-Fluoren-2-yl- (cont'd)
  - Liver Injury, Mouse, 78-3703
- Cholangioma
  - Adenosine Triphosphatase, 78-3709
  - Adenyl Cyclase, 78-3709
  - Monoamine Oxidase, 78-3709
- Chromatids
  - Ovary Cells, Hamster, 78-3700
- Dietary Fats
  - Ames Test, 78-3701
  - Enzyme Activation, 78-3701
- DNA
  - Liver, Rat, 78-3708
- Ethane, 1,1,1-Trichloro-2,2-bis(*p*-chlorophenyl)-
  - Carcinogenic Activity, 78-3711
  - Hepatotoxicity, Rat, 78-3711
- Hyperplasia
  - Gluconic Acid, Iron Salt, 78-3710
  - Liver, Rat, 78-3710
  - 8-Quinolinol, 78-3710
- Liver Neoplasms
  - Cephalins, 78-3706
  - Lecithins, 78-3706
  - Precancerous Conditions, 78-3710
- Liver, Rat
  - Sedimentation Analysis, Nuclei, 78-3708
- Microsomes, Liver
  - Lipids, 78-3706
- Mitochondria, Liver
  - Enzymatic Activity, 78-3709
- Ploidies
  - Liver, Rat, 78-3708

Acetamide, *N*-(5-Sulfamoyl-1,3,4-thiadiazol-2-yl)-
- Bone Neoplasms
  - Teratoid Tumor, 78-3712
- Teratoid Tumor
  - Case Report, Neonate, 78-3712

Acetanilide, 4'-Hydroxy-
- Urogenital Neoplasms
  - Carcinogenic Metabolite, 78-4145

Acetazolamide
- *see* Acetamide, *N*-(5-Sulfamoyl-1,3,4-thiadiazol-2-yl)-

Acetic Acid, Iodo-
- Cell Membrane
  - LETS Protein, 78-3735
- Glucose, 2-Deoxy-
  - Metabolism, Chick Embryo Fibroblasts, 78-3735

Acetic Acid, Methylnitrosaminomethyl Ester
- HeLa Cells
  - Nuclear Size, 78-3900

Acetic Acid, Vinyl Ester, Polymers
- DNA Replication
  - Macrophages, 78-3943
- Foreign Bodies
  - DNA Replication, 78-3943
  - Macrophages, 78-3943
  - Precancerous Conditions, 78-3943

Acetohydroxamic Acid, *N*-Fluoren-2-yl-
- Ames Test
  - Mutagenic Activity, 78-3701

Acetohydroxamic Acid, *N*-Fluoren-2-yl- (cont'd)
- Chromatids
  - Cells, Cultured, 78-3702
  - Ovary Cells, Hamster, 78-3700
- Dietary Fats
  - Ames Test, 78-3701
  - Enzyme Activation, 78-3701
- Selenious Acid, Disodium Salt
  - Chromatids, 78-3702

***p*-Acetophenetidide, *N*-Hydroxy-**
- Urogenital Neoplasms
  - Carcinogenic Metabolite, 78-4145

***p*-Acetophenetidide**
- Anemia, Hemolytic
  - Epidemiology, Review, 78-3638
- Bladder Neoplasms
  - 1-Butanol, 4-(Butylnitrosamino)-, 78-3896
- 1-Butanol, 4-(Butylnitrosamino)-
  - Co-carcinogenic Activity, 78-3896
- Hyperplasia
  - Bladder, 78-3695
  - Bladder, Rat, 78-3896
  - Wounds and Injuries, 78-3695
- Urogenital Neoplasms
  - Carcinogenic Activity, Review, 78-3638
  - Carcinogenic Metabolite, 78-4145
  - Choriocarcinoma, 78-4145
  - Epidemiology, 78-4145
  - Epidemiology, Review, 78-3638
  - Sarcoma, 78-4145

Acetophenone, 3',4'-Methylenedioxy-
- Benzene, 3'-Hydroxy-1,2-(methylenedioxy)-4-propenyl-
  - Metabolism, Rat, 78-3782

Acetoxydimethylnitrosamine
- *see* Acetic Acid, Methylnitrosaminomethyl Ester

Acrolein
- Smoke Condensate
  - Quantitation Method, 78-3698

Acrylamide, 2-(2-Furyl)-3-(5-nitro-2-furyl)-
- Chromosome Aberrations
  - Mutagenic Activity, Embryo, Hamster, 78-3696
- Guanine, 8-Aza-
  - Mutagenic Activity, Embryo, Hamster, 78-3696
- Purine-6(1*H*)-thione, 2-Amino-
  - Mutagenic Activity, Embryo, Hamster, 78-3696

Acrylonitrile
- Ames Test
  - Histidine Reversion, 78-3697
- Aroclor 1254
  - Mutagenic Activity, 78-3697
- 1,3-Butadiene
  - Mutagenic Activity, 78-3697
- Cholanthrene, 3-Methyl-
  - Mutagenic Activity, 78-3697
- Microsomes, Liver
  - Ames Test, 78-3697
  - Mutagenic Activity, 78-3697
- Styrene
  - Mutagenic Activity, 78-3697

Actinomycin D
- Carcinogenic Activity
  - Antineoplastic Agents, Review, 78-3639
- Cell Transformation, Neoplastic

Actinomycin D (cont'd)
  - Hybrid Cells, 78-4198
- Hybrid Cells
  - Cell Survival, 78-4198

Adenine
- Butyric Acid, 2-Amino-4-(ethylthio)-
  - Ovalbumin, 78-3645

Adenocarcinoma
- Bronchial Neoplasms
  - Ether, Bis(chloromethyl)-, 78-3814
  - Ethylene, Chloro-, 78-3814
- Cervix Neoplasms
  - Virus-Like Particles, 78-4055
- Colonic Neoplasms
  - Urea, Methyl Nitroso-, 78-3902
- Digestive System Neoplasms
  - Epidemiology, Sheep, 78-4138
- Intestinal Neoplasms
  - Colitis, Ulcerative, 78-4093
  - Methanol, (Methyl-*ONN*-azoxy)-, Acetate (Ester) 78-3858
- Kidney Neoplasms
  - Arsenic, 78-3693
  - 2-Imidazolidinone, 1-(5-Nitro-2-thiazolyl)-, 78-3832
  - Neoplasms, Multiple Primary, 78-3693
- Laminaran
  - Neoplasm Metastasis, 78-4081
  - Transplantation Immunology, 78-4081
- Lung Neoplasms
  - Epidemiology, Israel, 78-4175
  - Phthalazine, 1-Hydrazino-, 78-3839
- Neoplasm Regression, Spontaneous
  - Case Report, Review, 78-3666
- Nose Neoplasms
  - Epidemiology, 78-4112
  - Occupational Hazard, 78-4112
- Ovarian Neoplasms
  - Radiation, Ionizing, 78-3922
- Pancreatic Neoplasms
  - Dipropylamine, 2,2'-Dioxo-*N*-nitroso-, 78-3894
  - Histological Study, 78-3894
  - Neoplasm Metastasis, 78-4122
- Paranasal Sinus Neoplasms
  - Epidemiology, 78-4112
  - Occupational Hazard, 78-4112
- Respiratory Tract Neoplasms
  - Nicotine, 1'-Nitroso-1'-demethyl-, 78-3630
- Stomach Neoplasms
  - Gastritis, 78-4125
  - Guanidine, 1-Methyl-3-nitro-1-nitroso-, 78-3872 78-3873, 78-3876, 78-4126
  - Neoplasm Metastasis, 78-4122
- Uterine Neoplasms
  - Estrogens, 78-3796
- Vaginal Neoplasms
  - 4,4'-Stilbenediol, α,α'-Diethyl-, 78-3795

Adenocarcinoma, Mucinous
- *see* Carcinoma, Mucinous

Adenoma
- Colonic Neoplasms
  - Hydrazine, 1,2-Dimethyl-, 78-3843
- Kidney Neoplasms
  - 2-Imidazolidinone, 1-(5-Nitro-2-thiazolyl)-, 78-3832
- Liver Neoplasms
  - Androst-4-en-3-one, 17β-Hydroxy-17-methyl-

Adenoma (cont'd)
- Androst-4-en-3-one, 17β-Hydroxy-17-methyl- 78-3799
- Lung Neoplasms
  - Benzo(a)pyrene, 7,8-Dihydro-7,8-dihydroxy- 78-3763
  - Phthalazine, 1-Hydrazino-, 78-3839
  - Proline, 4-Hydroxy-1-nitroso-, 78-3634
  - Proline, 1-Nitroso-, 78-3634
  - Pyrrolidine, 1-Nitroso-, 78-3631
- Ovarian Neoplasms
  - Radiation, Ionizing, 78-3922
- Pituitary Neoplasms
  - Radiation, Ionizing, 78-3918
- Respiratory Tract Neoplasms
  - Nicotine, 1′-Nitroso-1′-demethyl-, 78-3630

Adenosine Cyclic 3′,5′ Monophosphate
- Benz(a)anthracene, 7,12-Dimethyl-
  - 12-*O*-Tetradecanoylphorbol-13-acetate, 78-3742
- Skin Neoplasms
  - 12-*O*-Tetradecanoylphorbol-13-acetate, 78-3742
- 12-*O*-Tetradecanoylphorbol-13-acetate
  - Epidermis, Mouse, 78-3742

Adenosine Diphosphate
- Hydrazine
  - Mitochondria, Liver, 78-3845

Adenosine Triphosphatase
- 1,1′-Biphenyl, 2,2′,5,5′-Tetrachloro-
  - Enzymatic Activity, 78-3720
- 1,1′-Biphenyl, 2,2′,5,5′-Tetrachloro-, 4-Hydroxy-
  - Enzymatic Activity, 78-3720
- 1,1′-Biphenyl, 2,2′,5,5′-Tetrachloro-, 3,4-Oxide
  - Enzymatic Activity, 78-3720
- Butyric Acid, 2-Amino-4-(ethylthio)-
  - Liver, Rat, Review, 78-3645
- Cholangioma
  - Acetamide, *N*-Fluoren-2-yl-, 78-3709
- Hepatoma
  - Diethylamine, *N*-Nitroso-, 78-3709
- Hydrazine
  - Potassium, 78-3845

Adenosine Triphosphate
- Hydrazine
  - Mitochondria, Liver, 78-3845

Adenyl Cyclase
- Cholangioma
  - Acetamide, *N*-Fluoren-2-yl-, 78-3709
- Hepatoma
  - Diethylamine, *N*-Nitroso-, 78-3709
- Melanoma
  - Corticotropin, 78-4099
  - Enzyme Activation, Hormonal, 78-4099
  - Metastatic Potential, 78-4099
  - MSH, 78-4099
  - Prostaglandins E, 78-4099

Adipose Tissue
- Breast Neoplasms
  - Androst-4-ene-3,17-dione, 78-4131
  - Carcinogen, Lipid-Soluble, 78-3663
  - Epidemiology, 78-3663, 78-4131
  - Estrone, 78-4131
- Immunity, Cellular
  - Rat, Nude, 78-4078

Adrenal Gland Neoplasms
- Nephroblastoma
  - Neoplasms, Multiple Primary, 78-4121
- Radiation, Ionizing
  - Parabiosis, Rat, 78-3918
- Virus, Murine Leukemia
  - Mouse, Hybrid, 78-3969

Adriamycin
- Ames Test
  - Mutagenic Activity, 78-3725
- Carcinogenic Activity
  - Antineoplastic Agents, Review, 78-3639

Aflatoxicol
- Aflatoxin B1
  - Carcinogenic Metabolite, 78-3687

Aflatoxin B1
- Aflatoxicol
  - Carcinogenic Metabolite, 78-3687
- Ames Test
  - *Salmo gairdneri*, 78-3685
- Aroclor 1242
  - Mutagenic Activity, 78-3685
- Aroclor 1254
  - Mutagenic Activity, 78-3685

2-Propanol, 1-Amino-
  1,3-Oxazolidine, 5-Methyl-*N*-nitroso-
    Formation, Cutting Fluid, 78-3899

1-Propanone, 2-Methyl-1,2-di-3-pyridyl-, Tartrate
  Benzo(a)pyrene-3,6-dione
    Metabolism, 78-3800
    Microsomes, Liver, 78-3800

Propene, 3-Chloro-
  Escherichia coli
    DNA, 78-3826
  Saccharomyces cerevisiae
    Chromosome Aberrations, 78-3826
  Salmonella typhimurium
    Mutagenic Activity, 78-3826

Propionic Acid, 2-(*p*-Chlorophenoxy)-2-methyl-, Ethyl Ester
  Benzenamine, *N*,*N*-Dimethyl-4-((3-methylphenyl)azo)-
    D-Amino Acid Oxidase, 78-3790
    Catalase, 78-3790
    Urate Oxidase, 78-3790
  Hepatoma
    Enzymatic Activity, 78-3790

Prostaglandins
  Phorbol 12,13-Didecanoate
    Cycloheximide, 78-3740
    Indole-3-acetic Acid, 1-(*p*-Chlorobenzoyl)-5-methoxy-2-methyl-, 78-3740
  12-*O*-Tetradecanoylphorbol-13-acetate
    Cortisol, 78-3740
    Cycloheximide, 78-3740
    Indole-3-acetic Acid, 1-(*p*-Chlorobenzoyl)-5-methoxy-2-methyl-, 78-3740

Prostaglandins E
  Benz(a)anthracene, 7,12-Dimethyl-
    Macrophages, 78-3741
  Bladder Neoplasms
    Antibody-Dependent Cytotoxicity, 78-4068
    Immunity, Cellular, 78-4068
    Lymphocytes, 78-4068
  Carcinoma, Epidermoid

Prostaglandins E (cont'd)
- Cholanthrene, 3-Methyl-, 78-3731, 78-3733
  - Ultrastructural Study, Mouse, 78-3733
- Cholanthrene, 3-Methyl-
  - Co-carcinogenic Activity, 78-3731, 78-3733
- Diterpene Esters
  - Macrophages, 78-3741
- Lymphocytes
  - Antitumor Activity, 78-4068
- Melanoma
  - Adenyl Cyclase, 78-4099
- Nucleic Acids
  - Co-carcinogenic Activity, 78-3731, 78-3733
- Phorbol 12,13-Didecanoate
  - Canine Kidney Cells, 78-3740
- Skin Neoplasms
  - Cholanthrene, 3-Methyl-, 78-3731, 78-3733
- 12-*O*-Tetradecanoylphorbol-13-acetate
  - Canine Kidney Cells, 78-3740
  - Cell Differentiation, 78-3737
  - Macrophages, 78-3741

Prostaglandins F
- Carcinoma, Epidermoid
  - Cholanthrene, 3-Methyl-, 78-3731, 78-3733
  - Ultrastructural Study, Mouse, 78-3733
- Cholanthrene, 3-Methyl-
  - Co-carcinogenic Activity, 78-3731, 78-3733
- Nucleic Acids
  - Co-carcinogenic Activity, 78-3733
- Phorbol 12,13-Didecanoate
  - Canine Kidney Cells, 78-3740
- Skin Neoplasms
  - Cholanthrene, 3-Methyl-, 78-3731, 78-3733

Prostatic Neoplasms
- Age Factors
  - Epidemiology, 78-3664
  - Epidemiology, France, 78-4139

Protamine
- Cervix Neoplasms
  - Sperm Proteins, 78-4148
- Sperm Proteins
  - Carcinogenic Potential, 78-4148

Proteins
- Carcinogen, Chemical
  - Binding, Review, 78-3605
- Ethyl Alcohol
  - Liver, Mouse, 78-3808

Pseudourea, (2-Aminoethyl)-2-thio-, Dihydrobromide
- *p*-Benzoquinone, 2,3,5-Tris(1-aziridinyl)-
  - Chromatids, 78-3801

Psoralen, 8-Methoxy-
- Xeroderma Pigmentosum
  - DNA Repair, 78-3914

Psychotropic Drugs
- Cervix Neoplasms
  - Epidemiology, 78-4146

Pulmonary Fibrosis
- Asbestos
  - Inhalation Study, Baboon, 78-3688
- Plutonium Oxide
  - Collagen, 78-3939
  - Dose-Response Study, 78-3939
  - Inhalation Study, Rat, 78-3939

Pulmonary Fibrosis (cont'd)
  - Precancerous Conditions, 78-3939
  - Uronic Acids, 78-3939

Purine, 2-Amino-6-methoxy-
- Dimethylamine, *N*-Nitroso-
  - DNA, Liver, Kidney, 78-3886
  - Enzymatic Removal, 78-3886
- Urea, Methyl Nitroso-
  - DNA, Liver, Kidney, 78-3886

Purine-6-thiol
- Carcinogenic Activity
  - Antineoplastic Agents, Review, 78-3639

Purine-6(1*H*)-thione, 2-Amino-
- Acrylamide, 2-(2-Furyl)-3-(5-nitro-2-furyl)-
  - Mutagenic Activity, Embryo, Hamster, 78-3696

Purpura
- Androst-4-en-3-one, 17β-Hydroxy-17-methyl-
  - Liver, 78-3799

Putrescine
- Gastrointestinal Diseases
  - Gastric Juice, 78-3880

Pyridine, 1-Nitroso-1,2,3,6-tetrahydro-
- Bacteria
  - Mutagenic Activity, 78-3892
- Microsomes, Liver
  - Mutagenic Activity, 78-3892

5*H*-Pyrido(4,3-*b*)indole, 3-Amino-1,4-dimethyl-
- Tryptophan
  - Mutagenic Pyrolysates, 78-3717

5*H*-Pyrido(4,3-*b*)indole, 3-Amino-1-methyl-
- Tryptophan
  - Mutagenic Pyrolysates, 78-3717

4,6(1*H*,5*H*)-Pyrimidinedione, 5-Ethyldihydro-5-phenyl-
- Liver Neoplasms
  - Anticonvulsants, 78-3716

Pyrrolidine, 3-Hydroxy-1-nitroso-
- Food Contamination
  - Quantitation Method, 78-3890

Pyrrolidine, 1-Nitroso-
- Bacteria
  - Mutagenic Activity, Review, 78-3631
- Cholangioma
  - Carcinogenic Activity, Rat, Review, 78-3631

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations or citations of significant carcinogenesis articles collected from the current major biomedical sources of world literature. This service is provided by the National Cancer Institute through a contract with the Franklin Research Center for preparation of the publication, under Contract No. NOI-CP-75885 with the National Cancer Institute, U.S. Department of Health, Education and Welfare. Published and distributed by the Franklin Institute Press^{SM}.

SUBSCRIPTIONS

For sale by The Franklin Institute Press, Box 2266, Philadelphia, PA 19103. Subscription rate for Volume 16, consisting of 12 monthly issues and a cumulative index is $75.00, Domestic and $90.00, Foreign. Check should be made payable to The Franklin Institute Press.

Maruzen Co., Ltd., 3-10, Nihonbashi 2-Chome, Tokyo 103, Japan, is the exclusive distributor of CARCINOGENESIS ABSTRACTS in Japan.

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations, or citations of significant cancer articles collected from the current major biomedical sources of the world literature. This service is provided by the National Cancer Institute through a contract with Franklin Research Center for preparation of the publication.

FREQUENCY OF PUBLICATION: *CARCINOGENESIS ABSTRACTS*, Volume 15, is published in 12 monthly issues with indexes, plus a cumulative index.

ABBREVIATIONS

JOURNAL names are abbreviated according to the *List of Journals Indexed in Index Medicus, Abbreviation Listing*. If the journal is not listed in this, abbreviations are derived from the *International List of Periodical Title Word Abbreviations.*

LANGUAGE of the article is indicated in parentheses after the title and is represented by a three-letter code. The source for these codes is *MARC Manuals Used by the Library of Congress*, pages 183-187.

ABBREVIATIONS used in abstracts:

A	angstrom(s)
ACTH	adrenocorticotropic hormone
ADP	adenosine diphosphate
AMP	adenosine monophosphate
ATP	adenosine triphosphate
approx	approximately
av	average
BCG	bacillus Calmette-Guerin
bid	twice daily
C	degree(s) centigrade
cal	calorie(s)
kcal	kilocalorie(s)

X	times
yr	year(s)

8-4201 **Translational Products of Type-C RNA Tumor Viruses.** (Eng) Stephenson, J. R. (Lab. RNA umor Viruses, NIH, Bethesda, MD, 20014); DeVare, S. G.; eynolds, F. H. *Adv Cancer Res* 27: 1-53; 1978.

ecent research on the translational products of C-type RNA umor viruses is reviewed. Topics covered include: C-type iral genome structure and complexity, proteins of C-type NA tumor viruses, genetic mapping of the C-type RNA umor virus genome, relatedness of structural proteins coded or by leukemia and sarcoma C-type viral genomes, and B-nd D-type oncornavirus structural proteins. (357 refs.)

8-4202 **Characterization of Human Papilloma Viruses and Their Possible Role in Human Tumors.** Eng) zur Hausen, H. (Institut fur Virologie, Zentrum fur Hygiene, Universitat Freiburg, Hermann-Herder-Strasse 11, 8 Freiburg, W. Germany); Gissman, L.; Pfister, H. *In: Cha-acterization and Treatment of Human Tumours. Proceedings of the Seventh International Symposium on the Biological Characterization of Human Tumours held in Budapest, April 13-15, 1977.* Davis, W.; Harrap, K. R., eds. (Amsterdam: Excerpta Medica): Advances in Tumour Prevention, Detection and Characterization. Vol. 4, 332 pp.; 20-21; 1978.

Recent studies on the heterogeneity of human papilloma viruses (HPV) are reviewed. There may be two distinct types of HPV in common warts. Studies of the roles of HPV in condylomata acuminata are suggestive of a role of human genital wart viruses in genital cancer. (8 refs.)

78-4203 **The Repair of DNA Modified by Cytotoxic, Mutagenic, and Carcinogenic Chemicals.** (Eng) Roberts, J. J. (Inst. Cancer Res., Royal Cancer Hosp., London SW3, England). *Adv Radiat Biol* 17: 211-436; 1978.

In the first part of this extensive review, the interaction of various compounds with cellular DNA and the biochemical and biological consequences in a variety of cell systems are surveyed. DNA is the principal target for several chemotherapeutic cytotoxic agents as well as known carcinogens. Two mechanisms that could produce required mutation(s) to malignancy are proposed. In the first, chemically-induced mutations replicate, resulting in further damage to the DNA. The mechanism assumes a direct relationship between this damage in newly replicated DNA and cell death, chromosome aberrations, and mutations. Modifications to DNA and/or the associated chromosome aberrations are likely to be amplified during subsequent cell divisions and lead to continuing chromosome instability. Eventually, some of these changes will lead to the expression of properties of malignancy. With respect to the second mechanism, direct-acting cytotoxic agents and the active forms of some carcinogens produce a characteristic cytotoxicity by electrophilic reaction with the cellular DNA, resulting in imperfect templates for DNA synthesis. The environment of normal, unreacted cells will be modified by the presence of enlarged and dying cells, possibly over a long time. The expected restorative hyperplasia will probably differ from that following damage by other agents; ie, it may lack the normal regulatory feedback controls involved in homeostasis. Under these abnormal growth conditions, cell division is more likely to give rise to nondisjunction and chromosome aberrations in otherwise normal, surviving cells. Further changes will result in an uncontrolled or mutated malignant cell. The postulated abnormal restorative hyperplasia occurring in response to this specific toxicity could, alternatively, permit epigenetic changes akin to differentiation. The second part of the review covers excision and postreplication repair of chemically modified DNA and genetic factors and DNA repair. (867 refs)

78-4204 **Progression of Tumours and Non-neoplastic Disorders as Manifestations of a Common Biological Phenomenon.** (Eng) Burch, P. R. (Dept. Medical Physics, General Infirmary, Leeds LS1 3EX, England). *Med Hypotheses* 4(2): 101-110; 1978.

A mechanism for the progression of both neoplastic and non-neoplastic disorders is proposed. It is suggested that all well-defined diseases and conditions that exhibit a reproducible age distribution satisfying certain statistical criteria should be regarded as autoaggressive disorders. These disorders are initiated in genetically predisposed persons when one or more stem cells of the central system of growth control have each acquired a specific complement of somatic gene mutations. A specifically mutant stem cell propagates a forbidden clone of descendant cells. These cells, or their secreted humoral products, attach target cells at one or more anatomical locations. Progression of the disease is the result of the random formation of more forbidden clones that attack more target cells. It is proposed that the stepwise progression of neoplastic disease resembles the similar progression in non-neoplastic disorders. The random event that initiates the fatal crisis in neoplastic diseases may arise in a cell derived from the proliferating clone or in some cell either belonging to or deriving from the central system of growth control. This proposed mechanism is related to events in the transition of multiple benign polyps of the large intestine to carcinoma of the large intestine, the progression of tumors in the uterine cervix, Parkinsonism, and male baldness. (23 refs)

78-4205 **Iatrogenic Leukemia.** (Dut) Nieweg, H. O. (No affiliation given). *Ned Tijdschr Geneeskd* 122(12): 398-401; 1978.

In view of the leukemogenic effects of alkylating drugs, their use should be limited to malignant diseases with poor prognosis, such as multiple myeloma, Hodgkin's disease with hematogenous spread, and metastatic ovarian carcinoma. (11 refs)

78-4206 **Iatrogenic Leukemia.** (Dut) van Swaay, H. (Zwolle, Netherlands). *Ned Tijdschr Geneeskd* 122(22): 804; 1978.

Iatrogenic leukemia may result from treatment with ionizing radiation or chemical agents, such as cytostatic alkylating compounds, and it is more common in persons with the following hereditary diseases: Bloom's syndrome, Fanconi's anemia, ataxia telangiectasia, and Down's syndrome. Individuals with an abnormal number of chromosome aberrations have a higher risk of leukemia. It is concluded that iatrogenic factors are related to the etiology of leukemia and that several types of these factors are suspect. (7 refs)

78-4207 **Pathogenesis of Chronic Myeloid Leukemia.** (Por) Jamra, M. (Dep. Clin. Medica, Fac. Medicina de Ribeirao Preto, Ribeirao Preto, Brazil). *Rev Hosp Clin Fac Med Sao Paul* 33(1): 52-56; 1978.

Studies on the pathogenesis of chronic myeloid leukemia are reviewed with special regard to the role of chromosome aberrations and of the Philadelphia chromosome. (60 refs.)

78-4208 **Gestational Trophoblastic Disease: Origin of Choriocarcinoma, Invasive Mole and Choriocarcinoma Associated with Hydatidiform Mole, and Some Immunologic Aspects.** (Eng) Brewer, J. I. (Dept. Obstetrics and Gynecology, Northwestern Univ. Medical Sch., Chicago, IL); Torok, E. E.; Kahan, B. D.; Stanhope, C. R.; Halpern, B. *Adv Cancer Res* 27: 89-147; 1978.

A review of cases in which choriocarcinoma occurred during a seemingly normal pregnancy in the presence of a fetus led to the concept that the origin of the neoplasm is in the trophoblast of an otherwise normal placenta. Also reviewed are data on the occurrence of invasive moles and choriocarcinomas in association with hydatidiform moles and the immunobiology of trophoblastic diseases. (94 refs.)

78-4209 **Asbestos and Respiratory Lesions.** (Fre) Roujeau, J. (Laboratoire Louis Fruhling, Service Central d'Anatomie et Cytologie pathologiques, Groupe Hospitalier Lariboisiere, 2, rue Ambroise-Pare, 75475 Paris Cedex 10, France); Lougnon, J. *Arch Anat Cytol Pathol (Paris)* 25(6): 431-437; 1977.

In a review of the histological changes in the lung observed in persons exposed to asbestos, the relationship between asbestos and cancer is discussed. Literature reports indicate that bronchogenic cancer is observed in 5.6%-15.2% and mesotheliomas in 0.18%-5.5% of persons with asbestosis who are autopsied. The incidence of gastrointestinal tumors is also elevated in asbestos workers (about 4 times that of the unexposed population). Carcinogenesis might be related to the chronic irritation caused by asbestos fibers or to the ease of fixation of carcinogens such as benzo(a)pyrene by the fibers after they have lost their magnesium. (25 refs)

78-4210 **Experimental Induction, Histology, an Ultrastructure of Hyperplasia and Neoplasia of the Urinary Bladder Epithelium.** (Eng) Hicks R. M. (Sch. Pathology, Middlesex Hosp. Medical Sch. London, England); Chowaniec, J. *Int Rev Exp Patho* 18: 199-280; 1978.

Experimental investigations of the early developmental stages of chemical-induced bladder cancer in laboratory animals are reviewed, along with the histology of the bladder. The histological appearance of normal transitional epithelium, reversible hyperplasia, irreversible hyperplasia and early neoplastic growth, and overt neoplasia are emphasized in an attempt to delineate some of the morphological and behavioral characteristics that distinguish benign hyperplasia from early neoplastic growth. (198 refs)

78-4211 **Does Bile Promote Extra-colonic Cancer** (Eng) Lowenfels, A. B. (Dept. Surgery Westchester County Medical Center, Valhalla, NY, 10595) *Lancet* 2(8083): 239-241; 1978.

Bile acids or their bacterial degradation products are believe to be involved as promoters or cocarcinogens in the pathogenesis of large bowel cancer. If this hypothesis is correct prolonged contact with infected bile might produce cancer in other portions of the alimentary tract. Of the biliary trac cancers, the gallbladder is the most common site, and gallstones are the major risk factor. Approx two-thirds of patients with biliary calculi have bacteriologically positive bil cultures. The incidence of bile duct cancer is high in patient with choledochal cysts, formations that impede bile flow an produce stasis. Bile duct cancer is associated with ulcerativ colitis and clonorchiasis. Portal bacteremia has been foun in ulcerative colitis, and bile duct cancer develops 10 yr earlier in patients with colitis than in patients without this disease. Clonorchiasis causes bile duct obstruction and sepsis Small bowel cancers are rare but found at sites (duodenum proximal jejunum) where there is exposure to high concentrations of bile. In addition, an association is suggested between regional enteritis and small bowel cancer. Gastric cancer is associated with bile gastritis, in which there is often bacterial overgrowth by anaerobic organisms. The risk of gastric cancer is increased after about a decade in Billroth I- and II-treated peptic ulcer patients, in whom bile freely enters the stomach. It is hypothesized that prolonged exposure to bile plus hypochlorhydria, which favors bacterial growth, increases the risk of gastric cancer. A common factor in a variety of alimentary cancers in young adults is stasis of bile or intestinal content. Finally, it is also likely that reflux of bile into the pancreas can promote pancreatic cancer. (33 refs.)

78-4212 **Development of Neoplasia in Children and the Elderly. Clinical, Biochemical, and Pathogenetic Considerations Related to Microcirculation.** (Ita) Malossi, M. (Primario Pediatra, Istito Ospedalieri di Trento, Centro Infantile "Angeli Custodi", Trento, Italy). *Recent Prog Med (Roma)* 64(5): 560-568; 1978.

Degenerative changes in the capillary system during old age may alter cell respiration, creating conditions that result in neoplastic transformation and abnormal cell growth. In vitro cell proliferation studies show that reduced O_2 supply increases polyamine synthesis and protease activity in cells and diminishes the production of antigenic proteins. In children, immune surveillance is effective because intercellular nutrition and transport function well; solid tumors are rare in childhood. (20 refs.)

78-4213 **Host Factors in the Development of Childhood Cancers.** (Eng) Li, F. P. (Sidney Farber Cancer Inst., 35 Binney St., Boston, MA, 02115). *Semin Oncol* 5(1): 17-23; 1978.

A review of the diverse host factors known to influence the development of childhood cancers reveals that they fall into three categories: single-gene defects, malformation syndromes, and familial cancers. The genetics of childhood cancer, birth defects and cancer, the familial aggregation of cancer, and host-environment interactions are surveyed. (89 refs)

78-4214 **Familial Cancer and Cancer Families.** (Eng) Anderson, D. E. (Dept. Biology, Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., 6723 Bertner Ave., Houston, TX, 77030). *Semin Oncol* 5(1): 11-16; 1978.

The clustering of intestinal, gastric, pancreatic, esophageal, and breast cancer in families is reviewed. The specific types of hereditary cancers can be identified by focusing on the histological types, sites of involvement, associated conditions, age of the patient at the time of diagnosis, tumor frequency, and the mode of inheritance. (44 refs)

78-4215 **Workshop on Persons at High Risk for Prostatic Cancer.** (Jpn) Watanabe, H. (Dept. Urology, Kyoto Prefectural Univ. Medicine, Kyoto, Japan); Mishina, T.; Hirayama, T.; Kato, H.; Kumamoto, Y.; Yoshida, O. *Acta Urol Jpn* 24(2): 129-144; 1978.

A review of the literature on prostate cancer epidemiology revealed racial differences in incidence and a high prevalence only in older patients. The frequency is highest among US blacks, but it is relatively high among US and European whites, compared with Orientals. In Japan, however, the incidence has increased markedly over the last two decades. Migration studies indicate that Japanese-Americans have a frequency intermediate between that of US whites and native Japanese. Although the cancer latency period is similar in the two races, the cancers of US whites or Japanese-Americans are more active histologically than those of the Japanese in Japan. Possible etiologic factors in prostatic cancer are sexual activity, heredity, cadmium pollution, and diet. (52 refs)

78-4216 **Susceptibility of Human Population Groups to Colon Cancer.** (Eng) Lipkin, M. (Memorial Sloan-Kettering Cancer Center, New York, NY). *Adv Cancer Res* 27: 281-304; 1978.

Literature on the susceptibility of various human population groups to colon cancer is reviewed. Topics discussed include the effects of the environment, inherited diseases, and proliferative abnormalities on susceptibility to colon cancer, recent immunologic studies, nuclear protein and enzyme alterations, studies of cutaneous cells, and examination of fecal contents. (90 refs.)

78-4217 **Epidemiology of Colorectal Cancer.** (Eng) Miller, A. B. (Epidemiology Unit, Natl. Cancer Inst. Canada, McMurrich Bldg, Univ. Toronto, Toronto, Ontario M5S 1A8, Canada). *Can J Surg* 21(3): 209-210; 1978.

International and Canadian data on colorectal cancer incidence are reviewed. The incidence is highest in Canada, with the United States not far behind. Japan and Nigeria have the lowest incidence rate. Evidence suggests that 80% of colorectal cancers would be preventable if the environmental factors involved in their etiology were identified and eliminated. There are differing sex ratios for cancer at different sites of the colon and rectum. Nutrition has an important bearing on the incidence of colorectal cancer, as determined by studies of migrant populations. The disease occurs more frequently in urban than in rural populations and in persons of higher socioeconomic status. Colorectal cancer also seems to be characteristic of populations with a short intestinal transit time and of persons who have a high excretion of fecal bile acids and steroids. (12 refs)

78-4218 **Dietary Carcinogens.** (Ger) Sailer, D. (Abteilung fur Stoffwechsel und Ernahrung, Medizinische Universitats-Klinik Erlangen, Krankenhausstrasse 12, D-8520 Erlangen, W. Germany). *Fortschr Med* 96(9): 446-449; 1978.

Studies of dietary carcinogens (polycyclic aromatic hydrocarbons, nitrosamines, and mycotoxins) are reviewed. Benzo(a)pyrene, a product of incomplete combustion, is found throughout the environment, especially in urban and industrial areas and near highways. It also occurs in air, plants, drinking water, fish, and in smoked, pickled, and roasted meat. Nitrosamines occur in certain foods, and they are also synthesized in the stomach. The synthesis is catalyzed by thiocyanate, which is present in high concentrations in the saliva, especially in that of smokers. Epidemiological studies revealed a correlation between nitrate and nitrite levels in food and the incidence of human tumors. A relationship was found between the incidence of liver tumors in humans and dietary aflatoxin intake. The use of alcohol, especially when combined with smoking, causes a considerable increase in the risk of cancer of the mouth, larynx, and esophagus, which is possibly due to the characteristic vitamin B deficiency in alcoholics. Relationships were also found between vitamin A deficiency and cancer of the cervix and between obesity and certain tumors. The increased incidence of gastric cancer among Japanese may be due to the consumption of rice polished with talc, a potential carcinogen. Talc crystals were found in tumor tissues from 6/7 gastric cancer patients in Japan. (35 refs)

78-4219 **Industrial Viewpoints on Cancer Caused by Metals as an Occupational Disease.** (Eng) Norseth, T. (Inst. Occupational Health, Oslo 3, Norway). *In: Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation.* Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 159-167; 1977.

Identifying a metal as carcinogenic is not sufficient, as the oxidation state of the metal, its interactions with other metals and chemicals, and factors, such as smoking habits may influence its carcinogenicity. Occupational exposure to metal carcinogens, ie, nickel, chromium, and arsenic, is difficult to record and characterize chemically. Using Ni as an example, a procedure for assessing carcinogenic risk due to metals in the work environment is presented. (16 refs.)

78-4220 **The Importance of Asbestos as a Harmful Sub
stance in the Environment.** (Ger) Konetzke, G
W. (Sitzungsberichte der Akademie der Wissenschaften de
DDR, Berlin, E. Germany). *Sitzungsber Akad Wiss DD*
(2): 26-32; 1978.

Various aspects of exposure to asbestos, which can result i
the development of fibrosis and cancer of the respiratory trac
and lungs, are reviewed. At present, the health risks due t
asbestos in the atmosphere are low. (42 refs)

78-4221 **Atmospheric Pollution and Lung Cancer.** (Eng
Doll, R. (Univ. Oxford, 13 Norham Gardens
Oxford OX2 6PS, England). *Environ Health Perspect* 22
23-31; 1978.

Factors that might be responsible for the increase
incidence of lung cancer in urban compared with rur
areas are discussed. The excess cannot be accounte
for by specific occupational hazards, but some o
it might be due to the presence of carcinogens in urba
air. The excess cannot be wholly due to such agent
because it is small and variable in nonsmokers. Occu
pational studies confirm that pollutants present in tow
air are capable of causing lung cancer in man and suggest tha
the pollutants and cigarette smoke act synergistically. Lun
cancer mortality trends in young and middle-aged men i
England and Wales support the hypothesis that atmospheri
pollution has contributed to the disease. In the absence o
cigarette smoking, the combined effect of all atmospheric carcinogens is not responsible for >5 cases of lung cancer/
100,000 persons/yr in European populations. (31 refs)

78-4222 **Late Effects of Air Pollution with Special Reference to Lung Cancer.** (Eng) Friberg, L. (Dept.
Environmental Hygiene, Karolinska Inst., 104 01 Stoc
holm 60, Sweden); Cederlof, R. *Environ Health Perspe*
22: 45-66; 1978.

Epidemiological and experimental studies of the late effects
of air pollution are reviewed with emphasis on lung cancer.
Epidemiological studies have shown an increased incidence
of lung cancer in urban compared with rural areas; this is als
true for several other forms of cancer (pancreas, bladder, and
cervix uteri). General air pollution, while proportionately a
smaller factor in lung cancer than tobacco smoking, pro
bably contributes to 10%-20% of the lung canc
incidence in heavily polluted urban areas. Studies o
laboratory animals have shown that air pollutants ma
be carcinogenic. Application of condensates of th
particulate fraction of air pollutants to the skin o
animals has given rise to tumors. A number of pote
carcinogenic polycyclic organic substances have bee
isolated from the particulate fraction. Although inhal
tion experiments have been carried out with polycyclic hy-

drocarbons in pure form, no association between exposure and an increase in cancer frequency has been demonstrated. Such an association has been shown, however, under special experimental conditions. Despite problems in extrapolation of data on late effects from experimental systems to man, all substances that are carcinogenic in animals should be regarded as potential human carcinogens. (139 refs)

78-4223 **Air Pollution and Cancer: Risk Assessment Methodology and Epidemiological Evidence. Report of a Task Group.** (Eng) Cederlof, R. (No affiliation given). *Environ Health Perspect* 22: 1-12; 1978.

Current scientific knowledge about carcinogenic air pollutants is considered in relation to epidemiological data on lung cancer, and available methods for assessing cancer risks from experimental data are reviewed. Carcinogenic or cocarcinogenic chemical agents derived from the use of fossil fuels are present at higher levels in urban than in rural atmospheres. In risk assessment, positive results with a substance in a combination of appropriate short-term bioassays are indicative of possible carcinogenicity. In the absence of relevant dose-response data, the most appropriate way to estimate the lung cancer risk is to assume that it is directly proportional to the increase in dose. For small added doses, a simple linear dose-response curve, as used in radiation carcinogenesis, is appropriate. For larger added doses or special population groups already at high risk, other forms of relationship may need to be considered. Epidemiological evidence indicates that fossil fuel combustion products in ambient air, probably acting together with cigarette smoke, contribute to lung cancer in large urban areas (5-10 cases/100,000 males/yr). Urban-rural differences in the incidence of other cancers are well documented, but the role of air pollution in such differences is not known. (37 refs)

78-4224 **Applicability of Bacterial Models of DNA Repair and Recovery to UV-Irradiated Mammalian Cells.** (Eng) Hewitt, R. R. (Univ. Texas System Cancer Center M.D. Anderson Hosp. and Tumor Inst., Houston, TX); Meyn, R. E. *Adv Radiat Biol* 7: 153-179; 1978.

The repair of damage produced in DNA by UV irradiation of bacteria and mammalian cells was reviewed, and the applicability of a bacterial model to mammalian cells was evaluated. The bacterial model was not found to be strictly applicable, based on observations that (1) cells from different species exhibit widely differing capacities for dimer excision that are not reflected in their survival sensitivities; (2) variable relationships exist between dimer excision and excision repair, as indicated by repair replication or unscheduled DNA synthesis; and (3) equivalent sensitivities of the rate of DNA synthesis are seen in mammalian cells, including xeroderma pigmentosum cells, regardless of their survival sensitivities or capacities for excision repair. Since photoreactivation of survival has not been observed in mammalian cells, the role of pyrimidine dimers in lethality cannot be demonstrated rigorously in photoreactivation experiments similar to those performed in bacteria. The development of two separate models, one for human cells and one for all other mammalian species, implies species-specific differences in photochemistry, chromosome structure, enzymology, or cellular physiology that at present are not sufficiently obvious to justify this approach. It is likely that no one simple DNA repair and recovery model may be applied to all physical or chemical environmental hazards, if the model is to be specific about classifying different types of reparable DNA damage and their modes of repair. (117 refs)

78-4225 **Risk of Thyroid Cancer due to Diagnostic Doses of Radiation.** (Ger) Schmitz-Feuerhake, I. (Fachsektion Physik, Universitat Bremen, Bibliothekstrasse, 2800 Bremen, W. Germany); Batjer, K.; Prevot, H. *Fortschr Geb Roentgenstr Nuklearmed* 128(5): 622-627; 1978.

Diagnostic radioiodine and x-ray examinations of the thyroid have led to thyroid carcinoma as a late consequence in a surprisingly large number of subjects. An analysis of literature data on the radiation doses delivered in these instances indicates, under the assumption of a linear nonthreshold dose-effect relationship, that the risk of thyroid cancer can be estimated at 20-60 cases/10^6 diagnostic examinations per rad during the first 20 yr after exposure. Thus, the radioiodine test should be restricted to carefully selected individual cases. (39 refs)

78-4226 **Panel Discussion: Sources of Carcinogens.** (Eng) Albert, R. E. (Inst. Environmental Medicine, New York Univ. Medical Center, New York, NY); Upton, A. C.; Carnow, B. W.; Wynder, E. L. *Bull NY Acad Med* 54(4): 435-441; 1978.

A panel discussion of the effects of mammography on breast cancer risk and of cigarettes and other pollutants on lung cancer risk is presented. As a woman ages, her risk of breast cancer increases but the risk of a radiation-induced carcinoma decreases. With lung cancer, one cannot speak of a threshold value for cigarette smoking; only the total body burden of carcinogenic material is important. Since carcinogens abound in the air, their regulation will be difficult. (3 refs)

78-4227 **Energy, Environment, and Health: What Can We Learn from the Nuclear Experience? Fourteenth Failla Memorial Lecture.** (Eng) Richmond, C. R. (Assoc. Director for Biomedical and Environmental Sciences, Oak Ridge Natl. Lab., P.O. Box X, Oak Ridge, TN, 37830). *Radiat Res* 73(3): 395-419; 1978.

The effects of energy-related pollutants, both nuclear and nonnuclear, on environment and health are reviewed. A survey is made of the various types of radiations and the inorganic and organic pollutants that are carcinogens, mutagens, or teratogens. Problems in establishing dose-response curves for chronic low-level exposures to ionizing radiation are presented, along with the detection of, and establishment of standards for environmental pollutants in general. (43 refs)

78-4228 **Bedside Etiology of Childhood Cancer.** (Eng) Miller, R. W. (Clinical Epidemiology Branch, NCI, Bethesda, MD). *CA* 27(5): 273-280; 1978.

Important new observations about the origins of childhood cancer are often made by the practicing physician, and several are reviewed briefly. Many observations concern environmental factors, such as prenatal exposure to diethylstilbestrol and childhood exposure to ionizing radiation, therapeutic radiation, radioisotopes, androgenic anabolic steroids for aplastic anemia, asbestos, metals (lead, copper, zinc), and viruses (Epstein-Barr virus). Other observations concern host peculiarities that carry a high risk of certain neoplasms. They include chromosomal abnormality (leukemia, retinoblastoma); cell-mediated immunosuppression (lymphoma); congenital hemihypertrophy, Beckwith-Wiedemann syndrome, congenital aniridia, renal dysplasia in the subcapsular area of the kidney (Wilms' tumor); and gonadal dysgenesis and a Y-chromosome cell line (gonadoblastoma). Certain other neoplasms seem to aggregate excessively in families: these cancers may be of a single histologic type or of dissimilar cell types. Types of familial cancer found in the literature are reported. (52 refs)

78-4229 **Factors Influencing Mutagenic Potency In Vitro.** (Eng) Ashby, J. (Central Toxicology Lab., Imperial Chemical Industries, Ltd., Alderley Park, Nr. Macclesfield, Cheshire, England); Styles, J. A. *Nature* 274(5666): 20-22; 1978.

Attempts to compare carcinogenic potency with mutagenic potency in the *Salmonella typhimurium* assay should acknowledge the established variability of in vitro mutagenic effects. The mutagenic potency of a chemical in *Salmonella* is influenced by at least 14 major factors [eg, tester strain, test protocol (plate incorporation, liquid culture, etc), S-9 mix source (organ, species)]. As a result, over the last 3 yr, the responses for several compounds have changed from reproducibly negative to reproducibly positive after the test procedure was modified. In addition, some chemicals produce mutation in vitro through the formation of metabolites not associated with those that cause cancer in vivo [benzo(a)pyrene, 7,12-dimethylbenz(a)anthracene]. Furthermore, it is probable that most mutagens will give an in vitro response with a thousandfold range and that the limits of this range will be populated by a few very potent or very weak mutagens. It is necessary to decide which species of rodent and which test protocol most closely resemble the manner of xenobiotic transformation of chemicals in humans. Correlations between mutagenic and carcinogenic potency may be found in some specific cases, and these may prove useful as a research tool, but they could easily (and wrongly assume the mantle of an invariable correlation. (41 refs)

78-4230 **Carcinogenic Activity and Biological Effects in Short-term Tests: Quantitative Aspects.** (Eng) Bartsch, H. (Lyon, France). *Staub-Reinhalt Luft* 38(6): 240-244; 1978.

The scientific basis and the efficacy of short-term tests used to predict carcinogenic effects of chemicals in animals are briefly summarized. Because compounds that produce false-negative or false-positive results in one system do not necessarily give the same false results in a different short-term assay, it is advantageous to use multiple short-term tests having different end-points to overcome the pitfalls of the individual assay. Methodological problems affecting the qualitative correlations between carcinogenicity and the biological end-points in short-term tests are illustrated by the Salmonella/microsome mutagenicity assay. These problems include the pharmacokinetics of the active mutagen, mutagen specificity, metabolic activation, and activation of carcinogenesis through deconjugation by beta-glucosidase. False-positive results may be obtained when the activation of premutagens occurs through bacterial enzymes that are not present or operating with different substrate specificities in mammalian cells. In addition, base analogs are mutagenic but may not produce tumors in animals and the rapid detoxication of chemicals in an intact organism may not occur in vitro conditions. A brief summary of experimental data that do or do not support a correlation between the carcinogenic potency of a chemical and its activity as a mutagen in the Salmonella/microsome assay, or other short-term tests, is presented. Factors that affect numerical results in in vitro and in vivo tests include the assay conditions, the type of metabolic activation system, and the time span. Short-term tests can at best serve as qualitative indicators of the potential carcinogenicity of chemicals. (34 refs.)

78-4231 **Extrapolation of Carcinogenic Risk from Animal Experiments to Man.** (Eng) Ehrenberg, L. (Dept. Radiation Biology, Wallenberg Lab., Univ. Stockholm, Stockholm, Sweden); Holmberg, B. *Environ Health Perspect* 22: 33-35; 1978.

The hypothesis that one or more mutational events are involved in tumor initiation is supported not only by the strong, jualitative correlation between mutagenic and carcinogenic ictivities of chemicals, but also by certain reaction-kinetic considerations. Experiments with microorganisms, plants, ind animals suggest that a limiting step in tumor origin s one mutational event in one cell and that the dose-esponse curve is linear from dose zero onward. An nverse relationship between dose and latency time ias been observed frequently and has been taken as in indication that it should be possible to extrapolate o such a low dose that the mean latency time would exceed the expected lifetime of the species studied. Iowever, a small dose may give individual latency times vithin the expected lifetime, even though the mean latency ime for a group exceeds the life span. The most important contribution of dose-response studies is in the application of nathematical models to epidemiologic data. It should be emembered, however, that a deviation from the linear lose-response relationship, with a higher effectiveness at lower doses, may occur for radiation, urethane, and vinyl chloride. (23 refs)

8-4232 **Ways of Detecting Carcinogen Potential in Human Populations. How Good Is the Correlation?** Eng) Newill, V. A. (Medical Dept., Res. and Environmental Iealth Div., Exxon Corporation, Linden, NJ). *Cancer Bull* 9(6): 175-178; 1977.

The reliability of animal models for predicting the carcinogenicity of a given chemical in man is reviewed. A survey of the IARC (International Agency for Research on Cancer) nonographs indicates that for 124/196 chemicals studied, no uman case studies or epidemiological data exist. Of the 108 hemicals that were positive carcinogens in animals, only 14 vere known human carcinogens. In addition, in only 18 cases vere the chemicals considered negative by both animal creening and human data. However, when known carcinogens such as diethylstilbestrol were tested in animals after heir carcinogenicity in humans had been established, positive results were obtained. It appears reasonable to assume hat the lifetime cancer incidence resulting from chronic exposure in humans can be approximated for the lifetime incidence in animals exposed similarly to same total dose per ody wt. When the animal data are extrapolated to humans, hough, the limitations of the animal system must be understood. It is suggested that the data obtained from animal studies be used in regulatory decisions for human exposure evels. (7 refs)

8-4233 **Mechanisms of Metabolic Activation of Carcinogens.** (Eng) Kriek, E. (Chemical Carcinogenesis Div., Antoni van Leeuwenhoek-Huis, Netherlands Cancer Inst., Amsterdam, Netherlands). *In: Characterization and Treatment of Human Tumours. Proceedings of the Seventh International Symposium on the Biological Characterization of Human Tumours held in Budapest, April 13-15, 1977.* Davis, W.; Harrap, K. R., eds. (Amsterdam: Excerpta Medica): Advances in Tumour Prevention, Detection and Characterization. Vol. 4, 332 pp.; 51-57; 1978.

Studies of the metabolic activation of carcinogens are reviewed under the following topics: chemicals as initiators of carcinogenesis: formation of reactive intermediates: metabolism of nitrosamines, aromatic amines, and amides: and the nature of reaction products with DNA and their repair. Schemes of the metabolic activation of diethylnitrosamine, 1-acetoxydiethylnitrosamine, and N-hydroxy-2-acetylaminofluorene and of alkylation sites on the DNA helix are given. (25 refs.)

78-4234 **Genetic Hazards of Anesthetic Gases: An Epidemiologic Study. Prevention and Extrapolation from Experimental Test Systems (Meeting Abstract).** (Eng) Infante, P. F. (Natl. Inst. Occupational Safety Health, Room 515, Post Office Building, Cincinnati, OH). *Clin Genet* 13(1): 123; 1978. (no refs)

78-4235 **Limits and Possibilities of Animal Experiments with Carcinogenic Inhalants.** (Ger) Horn, K. H. (No affiliation given). *Akademie der Wissenschaften* (2): 52-62; 1978.

Animal inhalation studies with chemical carcinogens or cocarcinogens are reviewed and their relevance to cancer induction in humans is discussed. Current inhalation techniques are not completely reliable due to the short life span of the test animals (eg, rats and Syrian golden hamsters) and the long observation periods needed to approximate human exposures. With the development of more sophisticated inhalation equipment, more positive results may be obtained with definite carcinogens. Another difficulty with the inhalation method is the evaluation of a positive result; ie, whether a substance such as ferric trioxide is carcinogenic, cocarcinogenic, or causes cytopathological conditions that promote development. Intratracheal intubation and implantation techniques are more accurate in the production of respiratory tract tumors, and they are useful in screening possible carcinogenic inhalants. The system application method is adequate only when testing a known carcinogen whose activity (po or sc) is organ-specific in the test species. However, this technique is useful in that the exact dose can be applied and the synergistic and/or cocarcinogenic properties of the test substance can be ascertained. To relate respiratory tract carcinogenesis in man to animal experiments will require the perfection of application techniques and the identification of more suitable animal models. (61 refs.)

78-4236 **The Problem of Threshold Values for Carcinogens in the Atmosphere.** (Ger) Schramm, T. (No affiliation given); Teichmann, B. *Akademie der Wissenschaften* (2): 46-51; 1978.

The problem of no-effect levels and acceptable threshold values for atmospheric carcinogens is discussed. Although there seem to be no-effect levels and doses for certain carcinogens, it is impossible to predict individual threshold values, because of great individual variations, or to determine safe levels for the general population. The cancer risk can be reduced but not eliminated by setting technical concentration standards, at first in areas where max reduction of the atmospheric concentrations of carcinogens can be achieved at acceptable cost. (21 refs.)

78-4237 **Use of Cultured Human Cells in Short-Term Tests for Chemical Carcinogens.** (Eng) Stich, H. F. (Cancer Res. Centre, Univ. British Columbia, Vancouver, Canada); San, R. H.; Lam, P.; Koropatnick, J. *Environ Health Perspect* 22: 131-132; 1978.

The advantages of using cultured human cells as indicators in short-term assays for chemical carcinogens and DNA fragmentation/DNA repair as endpoints are considered. The chief advantage of this system is its adaptability to situations that prevail in humans. The interaction of chemical and physical agents can be studied, as can the effect of human viruses on the response of cells to chemical carcinogens. Two criticisms can be directed at this system: (1) studies have been performed exclusively on fibroblasts instead of the epidermal cells from which most human tumors arise; and (2) the assay uses cultured cells forced to grow on glass or plastic surfaces rather than human organ pieces. For the large-scale screening of carcinogens, combining (1) bioassays that are the most rapid, economic, and reproducible with (2) bioassays that closely simulate conditions prevailing in humans should increase their predictive value. (13 refs)

78-4238 **Estrogens and Endometrial Cancer (2 Letters to Editor).** (Eng) Novak, E. R. (3106 St. Paul St., Baltimore, MD, 21218); Kistner, R. W. *Obstet Gynecol* 51(2): 254-255; 1978.

Criticism is made of a previous article in which a causal role for estrogen in endometrial cancer was denied. Several cancerous or precancerous situations in which estrogen is extremely suspect are summarized. Furthermore, progesterone therapy following estrogen treatment will not prevent the development of adenocarcinoma. In rebuttal, it is stated that estrogen will be a factor only in 10%-12% of the predisposed women receiving estrogen therapy. (4 refs)

78-4239 **N-Nitrosofolic Acid.** (Eng) IARC Working Group (Lyon, France). *In: Some N-Nitroso Compounds.* Magee, P. N., Chairman (International Agency for Research on Cancer: Switzerland): IARC Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Humans. Vol. 17, 365 pp.; 217-220; 1978.

Data on the carcinogenicity of N-nitrosofolic acid (NFA) are reviewed. Ip injection of the compound into newborn mice resulted in an insignificant increase in tumors. NFA was mutagenic in several strains of *Salmonella typhimurium* in the presence of a rat liver microsomal fraction. There were data on human exposure. The carcinogenicity of NFA could not be evaluated on the basis of available data. (4 refs.)

78-4240 **The Carcinogenicity of Chloro Ethers and Related Compounds: A Brief Note.** (Eng) Nelson, N. (Inst. Environmental Medicine, New York Univ Medical Center, New York, NY, 10016). *In: Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation.* Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 115-118; 1977.

Experimental data on the mutagenicity and carcinogenicity of bis(chloromethyl)ether, chloromethyl methyl ether, dimethylcarbamoyl chloride, and diethylcarbamoyl chloride are reviewed briefly. (11 refs.)

78-4241 **Mutagenic, Carcinogenic, and Teratogenic Hazards Arising from Human Exposure to Plastics Additives.** (Eng) Withey, J. R. (Health Protection Branch, Bureau Chemical Safety, Toxicology Div., Ottawa K1A OL2, Canada). *In: Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation.* Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 219-241; 1977.

The mutagenic, carcinogenic, and teratogenic hazards arising from human exposure to plastics additives are reviewed. There are 10 major classes of additives: antioxidants, antistatic agents, blowing agents, colorants, flame retardants, free radical initiators, lubricants, plasticizers, solvents, and stabilizers. The nature of these chemical classes and species and the roles they play in a finished plastic product are discussed briefly. The antioxidants butylated hydroxyanisole and butylated hydroxytoluene appear to be noncarcinogenic and nonteratogenic, but both possess mutagenic potential. Benzoquinone and its derivatives have shown considerable antitumor activity against lymphoid leukemia L1210. Antistatic agents appear to pose little or no carcinogenic threat, but a teratogenic effect has been observed with acetyltrimethylammonium bromide in mice. Various forms of leukemia are associated with chronic exposure to blowing agents, some of which also produce liver and kidney lesions Carcinogenic colorants include 4-dimethylaminoazobenzene, 4-o-tolylazo-o-toluidine, 1-o-tolylazo-2-naphthol, 2,2′-azonaphthalene, Ponceau 3R, R-acid, and trypan blue. Some of these dyes may also be teratogenic. Among the flame retardants, halogenated aromatic hydrocarbons have little or no carcinogenic or teratogenic potential, but aliphatic halogenated hydrocarbons and halogenated monomers are well-documented carcinogens or suspected carcinogens. Organophosphate derivatives have weak mutagenic properties. No conclusive evidence has been established for the carcinogenic potential of free radical initiators, but many of these chemicals are highly suspect. There is little data on the toxicity or carcinogenic potential of lubricants; however, carcinogenesis has been linked to industrial exposure to waxes. Phthalates, used as plasticizers, are teratogenic and mutagenic, but no carcinogenic effects have been reported. Many industrial solvents are carcinogenic and teratogenic. Little is known about stabilizers and UV absorbers, except that they are highly toxic in cell culture tests. There is little literature on the testing of miscellaneous additives used in plastics with the exception of well-established carcinogenic hazards such as asbestos. (132 refs.)

78-4242 **Salbutamol: Lack of Evidence of Tumour Induction in Man (Letter to Editor).** (Eng) Finkel, M. J. (Dept. Health Education and Welfare, Public Health Service, Food and Drug Admin., Rockville, MD). *Br Med J* 1(6113): 649; 1978.

Salbutamol, a β-stimulant bronchodilator, causes mesovarian leiomyomas in rats, but no association of this or related compounds with leiomyomas in humans has been detected. Although it would be wrong to extrapolate these findings to all related compounds, it would also be wrong to dismiss these findings as species-specific. It is suggested that although some toxic manifestations are species-specific, humans should be considered equivalent to the least-favored species. (2 refs)

78-4243 **The Carcinogenicity of Organochlorine Pesticides.** (Eng) Epstein, S. S. (Sch. Public Health, Univ. Illinois Medical Center, Chicago, IL, 60612). *In: Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation.* Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 243-265; 1977.

The carcinogenicity of organochlorine pesticides (OCP) is reviewed.The 18 OCP have been proven to be carcinogenic include dieldrin, chlorobenzilate, endrin, kepone, methoxychlor, benzene hexachloride, dichlorodiphenyltrichloroe-reviewed. The 18 OCP which have been proved to be carcinogenic include dieldrin, chlorobenzilate, endrin, kepone, methoxychlor, benzene hexachloride, dichlorodiphenyltrichloroethane (DDT), lindane, pentachloronitrobenzene, perthane, dichlorodiphenyldichloroethane, aldrin, chlordane, ethylene dichloride, heptachlor, mirex, strobane, and toxaphene. Epidemiological studies were carried out to examine the relationships between chronic pesticide exposure and morbidity and mortality. Examination of age-adjusted mortality rates revealed a rising death rate, compared with a stable age-adjusted rate for the entire population. Men aged 35-44 yr with a long history of pesticide exposure had an excess death rate when compared to men in the state of Florida. Data from six studies in mice and seven studies in rats on the carcinogenicity of dieldrin and aldrin are summarized. Results of carcinogenicity studies on chlordane and heptachlor are also presented. Constraints in the generation and interpretation of carcinogenicity data are illustrated. Possible remedies for these constraints include the introduction of a disinterested advisory group or agency as an intermediary between manufacturers and commercial and other testing laboratories, and the development of independent nonprofit research centers concerned with the problems of consumer, occupational, and environmental safety. (33 refs.)

78-4244 **Antineoplastic Agents as Potential Carcinogens.** (Eng) Adamson, R. H. (Lab. Chemical Pharmacology, NCI, NIH, Bethesda, MD, 20014); Sieber, S. M. *In: Incidence of Cancer in Humans. Book A. Cold Spring Harbor Conferences on Cell Proliferation.* Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 429-443; 1977.

Literature data on the animal and human carcinogenicity of various antineoplastic agents are reviewed. Although no anticancer or immunosuppressive agent can actually be implicated as being carcinogenic in humans, the agents most frequently associated with neoplasia are melphalan, Imuran, and combinations such as the MOPP regimen (nitrogen mustard, vincristine, prednisone, procarbazine). Evaluation of the role of chemotherapy in the development of acute leukemia in cancer patients is complicated by the possibility that a patient with cancer is at high risk for developing multiple primary malignancies and the possibility that acute leukemia is part of the natural history of myeloma and Hodgkin's disease. The latter is only now becoming evident because of the increased survival due to chemotherapy. Further studies in animals, particularly in nonhuman primates, and careful monitoring of all patients treated with antineoplastic agents will provide a more accurate analysis of the carcinogenic potential of these drugs. (55 refs.)

78-4245 **Carcinogenesis in an Industrial Age (Meeting Abstract).** (Eng) Gronow, M. (Cancer Res. Unit, Univ. York, York, England). *Br J Radiol* 51(602): 149; 1978. (no refs)

78-4246 **The Special Relevance of Cancer.** (Eng) Tarr, J. (Toxcon Engineering Co., P.O. Box 57310, Webster, TX, 77598); Damme, C. *Chem Eng* 85(10): 86-89; 1978.

Problems in the identification and regulation of chemical carcinogens and their implications for the chemical process industries are summarized. Human chemical carcinogens and industrially important organic chemicals recognized or suspected as human carcinogens are listed. The Toxic Substances Control Act is the newest US environmental law likely to significantly affect the use and distribution of these chemicals. (no refs)

78-4247 **Are Physiological Oxygen Concentrations Mutagenic?** (Eng) Bruyninckx, W. J. (Laboratorium voor Fysiologische Scheikunde, Faculteit Diergeneeskunde, R.U.G., Casinoplein 24, B-9000, Ghent, Belgium); Mason, H. S.; Morse, S. A. *Nature* 274(5671): 606-607; 1978.

Oxygen-sensitive mutants of the *Salmonella typhimurium* histidine auxotroph strain TA100 were used to show that exposure of oxygen-sensitive cells to oxygen concentrations physiological for mammals can lead to mutation. Agar plates were incubated anaerobically at 37 C for 3-5 days or under 5% oxygen at 37 C for 2 days. Exposure to oxygen increased the frequency of histidine-dependent revertants significantly in 3/5 mutant strains. Although oxygen mutagenicity is improbable, but not impossible, in normal aerobic mammalian cells, higher rates of formation of reactive forms of oxygen or lower rates of their destruction could lead to significant rates of mutagenesis along with the molecular pathologies arising from mutation. (7 refs.)

78-4249 **Vinyl Chloride Carcinogenicity: An Experimental Model for Carcinogenesis Studies.** (Eng) Maltoni, C. (Inst. Oncology, Bologna, Italy 40138). *In: Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation.* Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 119-146; 1977.

The carcinogenicity of vinyl chloride (VC) was evaluated in Sprague-Dawley rats, Wistar rats, Swiss mice, and golden hamsters. In inhalation studies, 50-30,000 ppm VC produced Zymbal gland carcinomas, nephroblastomas, hepatic angiosarcomas (HAS) and angiosarcomas of other sites, sc angiomas, skin carcinomas, hepatomas, brain neuroblastomas, and mammary carcinomas in adult Sprague-Dawley rats after 52 wk of exposure. Rats exposed to only 25 ppm VC for 87 wk developed HAS. Reducing the length of treatment sharply reduced the onset of several tumor types, particularly HAS: when rats were treated for 5 wk at 10,000 and 6,000 ppm, no HAS were observed. VC also had a transplacental effect: exposure of pregnant rats to 10,000 or 6,000 ppm VC on days 12-18 of pregnancy produced VC-dependent tumors in the offspring. Newborn rats were also more susceptible to VC carcinogenesis than older ones. Exposure of Wistar rats to varying VC concentrations for 52 wk resulted in basically the same tumors as those produced in Sprague-Dawley rats. Exposure of Swiss mice to 50-10,000 ppm VC for 30 wk resulted in lung tumors, mammary carcinomas, HAS, vascular tumors of other types and/or sites, and epithelial tumors of the skin. In golden hamsters, the same VC concentrations resulted in HAS, skin trichoepitheliomas, melanomas, and forestomach epithelial tumors. In addition, the latency time of lymphomas was decreased from 82 wk (in controls) to 48 wk. Ingestion of 50, 16.65 or 3.33 mg/kg/day VC by Sprague-Dawley rats, 4-5 days/wk for 52 wk produced essentially the same spectrum of tumors as the inhalation studies. One nephroblastoma and one sc angiosarcoma were found among 240 Sprague-Dawley rats that had received one to four ip injections of 4.25 mg VC, and one nephroblastoma was found among 75 animals that had received the same dose sc. It is concluded that the neoplastic response to VC depends largely on the species and strain of animal and that age is also important with respect to tumor incidence and distribution. (5 refs.)

78-4250 **Resolution of Dose-Response Toxicity Data for Chemicals Requiring Metabolic Activation: Example--Vinyl Chloride.** (Eng) Gehring, P. J. (Health and Environmental Res., Dow Chemical USA, Midland, MI, 48640); Watanabe, P. G.; Park, C. N. *Toxicol Appl Pharmacol* 44(3): 581-591; 1978.

The concept that the toxicity of many chemicals may not be a function of exposure to the chemical per se but rather to a biotransformation product is illustrated with vinyl chloride (VC). In such a case, it is necessary to determine the amount of the chemical undergoing biotransformation as a function of dose or exposure before a meaningful dose-response relationship can be established. Male Sprague-Dawley rats were exposed via inhalation to 1.4-4,600 ppm VC for 6 hr, and the total amount of VC metabolized was determined. Activation to the toxic form followed apparent Michaelis-Menten kinetics. A logarithmic probability plot of the incidence of hepatic angiosarcoma vs the amount of VC transformed, rather than the exposure concentration of VC, was linear. Assuming no threshold dose, extrapolation of the data below the range of doses causing experimentally observable responses predicted a 0.01% hepatic angiosarcoma incidence in rats exposed to 4.6 ppm VC. Theoretical extension of the extrapolation to humans exposed daily for 8 hr to 1 ppm led to a predicted incidence of 1.5/100,000,000. This incidence, although likely an overestimate in the light of evidence for at least a practical threshold in both rats and humans, is less than that expected to occur spontaneously. Although this method of estimation is not without flaws, the rationale involved represents a new approach that utilizes more logic than current extrapolation methods. The concepts that evolved from this analysis reveal why pharmacokinetics must be considered in designing toxicology experiments as well as in interpreting the resulting data. (22 refs.)

78-4255 **The Effect of Dioxane on Crystalline Isocitric Dehydrogenase (ICDH).** (Eng) Baykut, F. (Faculty Chemistry, Istanbul Univ., Istanbul, Turkey); Sengun, A.; Enginun, M. *Chim Acta Turcica* 4(2): 173-180; 1976.

The effect of 1,4-dioxane on crystalline isocitric dehydrogenase (ICDH) activity was investigated spectrophotometrically at concentrations ranging from 0.1 to 100 μl/ml. The test mixture contained 0.01 M $MgCl_2$, 0.01 M DL-isocitrate trisodium salt, 7 mg/ml NAD, and 0.1 M Tris buffer at a pH of 7.6, 0.15 ml enzyme, and varying concentrations of dioxane. The control mixture contained all chemicals with the exception of the enzyme. ICDH activity increased at low concentrations of dioxane and reached a max value at 0.5 μg/ml. The enzyme activity then decreased gradually with increasing dioxane concentration up to 10 μl/ml and then leveled off, at values slightly below those of control, at dioxane concentrations up to 100 μl/ml. Although dioxane is claimed to be a hepatocarcinogen, these results show that it may have use in tumor therapy within a certain concentration range. (15 refs)

78-4256 **Role of Lipopolysaccharide in the Production of Plasma Cell Tumors in Mice Given Mineral Oil Injections.** (Eng) Platica, M. (Res. Inst. Hosp. Joint Diseases, Mount Sinai Sch. Medicine, New York, NY, 10035); Hollander, V. P. *Cancer Res* 38(3): 703-705; 1978.

The lipopolysaccharide (LPS) content of peritoneal fluids of female BALB/c mice given ip mineral oil or pristane (2,6,10,-14-tetramethylpentadecane) injections at 2, 4, and 6 mo and of normal mice was measured. Peritoneal fluids were collected from 1 to 23 mo after the beginning of treatment. They were passed through DEAE-Bio-Gel columns to remove an inhibitor to the *Limulus* amebocyte lysate (LAL) reaction and then were assayed for LPS by a spectrophotometric LAL test. The mean LPS content of control mice was 0.09 nanogram/ml. In the treated mice, the concentration of LPS correlated with time after the first oil injection. P-200 gel chromatography and heat stability of the active material were characteristic of LPS. The low concentrations of LPS found in the peritoneal fluids from mice given oil injections less than 2 mo before sampling suggest that LPS is not simply a contaminant from injection but arises from the chronic peritonitis that develops after oil treatment. These results are consistent with but do not prove the hypothesis that LPS plays an intermediate role in the pathogenesis of plasma cell tumors in the BALB/c mouse given oil injections. (21 refs)

78-4257 **Co-carcinogens from *Croton flavens* L. and the High Incidence of Esophageal Cancer in Curacao.** (Eng) Hecker, E. (Deutsches Krebsforschungszentrum, Institut fur Biochemie, Heidelberg, W. Germany); Weber, J. *In: Characterization and Treatment of Human Tumours. Proceedings of the Seventh International Symposium on the Biological Characterization of Human Tumours held in Budapest, April 13-15, 1977.* Davis, W.; Harrap, K. R., eds. (Amsterdam: Excerpta Medica): Advances in Tumour Prevention, Detection and Characterization. Vol. 4, 332 pp.; 72-75; 1977.

Several cocarcinogenic factors were isolated from the leaves and roots of the shrub *Croton flavens* L. on the island of Curacao. These findings strongly suggest that the exceptionally high rate of esophageal cancer in Curacao may be causally related to the cocarcinogenic tigliane derivatives found, because of the widespread local habits of brewing a tea from the leaves of this plant and chewing the roots. (13 refs.)

78-4258 **Aflatoxin B$_1$-2,3-dichloride as a Model of the Active Metabolite of Aflatoxin B$_1$ in Mutagenesis and Carcinogenesis.** (Eng) Fahmy, M. J. (Dept. Genetics, Inst. Cancer Res., Pollards Wood Res. Station, Nightingale Lane, Chalfont St. Giles, Buckinghamshire HP8 4SP, England); Fahmy, O. G.; Swenson, D. H. *Cancer Res* 38(8): 2608-2616; 1978.

The biological activities of aflatoxin B$_1$ 2,3-dichloride (AFB$_1$-Cl$_2$) and the parent mycotoxin aflatoxin B$_1$ (AFB$_1$) were compared in *Drosophila melanogaster* males. Mutagenicity was assayed for the whole X chromosome (recessive lethals and visibles), at specific euchromatic loci, and at representatives of the RNA genes, especially the ribosomal DNA sites. Survival studies of the males treated by injection showed that LD$_{50}$ levels of both compounds were reached at virtually the same molar doses and times after treatment, which indicates that chlorination of the mycotoxin did not alter its general toxicity to the whole organism. In contrast, the cytotoxic and mutagenic efficiencies of AFB$_1$-Cl$_2$ were considerably higher than those of AFB$_1$, and the differentials in these activities were more marked on the metabolically inert sperm than on the metabolizing earlier germ cell stages. The mutational spectra of AFB$_1$-Cl$_2$ and AFB$_1$ in vivo were identical to those previously ascertained after monofunctional alkylation, particularly with respect to the induction of mosaicism and selectivity for ribosomal DNA. These genetic results were consistent with the conclusion that AFB$_1$-Cl$_2$ is a model of the oxidative metabolite AFB$_1$ 2,3-oxide. Both induce their mutagenicity through reactions between C-2 of the AFB$_1$ residues and the bases of genetic DNA, especially the N-7 of guanine moieties. With AFB$_1$-Cl$_2$, the ribosomal DNA mutagenic selectivity index was of the same order as that of other direct and indirect alkylating carcinogens, but its absolute genetic activity, on a molar dose basis, was orders of magnitude higher than even the more genetically potent alkylating agents. (22 refs)

78-4259 **Fluorescence Studies of the Interactions of Serum Albumin and Rat Alpha$_1$-Fetoprotein with Aflatoxin B$_1$: Specificity and Binding Parameters.** (Eng) Evrain, C. (L.A. 87 C.N.R.S., U.E.R. des Saints-Peres, 45, rue des Saints-Peres, 75006 Paris, France); Cittanova, N.; Jayle, M. F. *Biochim Biophys Acta* 533(2): 408-414; 1978.

The interaction of bovine serum albumin (BSA) and rat α_1-fetoprotein (AFP) with aflatoxin B$_1$ (AFB$_1$) was followed by the fluorescence quenching of the protein in the presence of the ligand. In the BSA-AFB$_1$ system, the number of binding sites (n) wa 3.5 and the dissociation constant (K-d) was 3.1 ± 0.5 10^{-5} M; in the AFP-AFB$_1$ and anilinonaphthalen sulfonate competed for the same hydrophobic sites on BSA Fluorescence emission spectra of lysozymes, egg albumin and gamma globulin in the presence of AFB$_1$ indicated n specificity of the mycotoxin for albumin. (7 refs)

78-4260 **Aflatoxin Induced Inhibition of Protein Synthesis.** (Eng) Ramachandra Pai, M. (Dept. Biochemistry, Vallabhbhai Patel Chest Inst., Univ. Delhi, Delhi 110 007, India); Jayanthi Bai, N.; Venkitasubramanian, T. A. *Toxicon* 16(3): 283-287; 1978.

The effects of aflatoxin B$_1$ (AFB), aflatoxin G$_1$ (AFG), and aflatoxin M$_1$ (AFM) on hepatic protein synthesis were investigated in male Wistar rats. AFB, AFG, and AFM were injected ip in single doses of 6, 12, and 6 mg/kg, respectively. For in vivo studies, the rats received ^{14}C-leucine ip 24 hr after dosing, and they were sacrificed 3 hr later; for in vitro studies, the rats were sacrificed 24 hr after toxin administration. The protein level was lowest in AFB-treated rats. Decreases in the glycogen level were observed in AFB- and AFM-treated rats. All three aflatoxins markedly increased the amount of lipids, with AFB producing the max increase and AFG the minimum. In vivo protein synthesis in all three hepatic subcellular fractions (nuclear, mitochondrial, cytoplasmic) was inhibited significantly by AFM; that in the mitochondrial and cytoplasmic fractions was inhibited significantly by AFB. No inhibition was observed with AFG, in spite of its higher dose. The inhibitory effect of AFM was greater than that of AFB in all three fractions. In vitro, mitochondrial protein synthesis was inhibited significantly by AFG and AFM, but not by AFB; however, AFM and AFB, but not AFG, significantly inhibited cytoplasmic protein synthesis. The in vivo but not in vitro inhibition of mitochondrial protein synthesis by AFB could be due to its metabolic conversion in vivo to AFM. (25 refs)

78-4261 **In Vitro Conversion of Aflatoxin B$_1$ to Bacterial Mutagen(s) by Hepatic Microsomes of Rats on a Deficient Diet (Meeting Abstract).** (Eng) Suit, J. L. (Dept. Nutrition and Food Science, Center Cancer Res., Massachusetts Inst. Technology, Cambridge, MA, 02139); Rogers, A. E.; Jetten, M. E.; Luria, S. E. *Mutat Res* 53(1): 68; 1978. (no refs)

78-4262 **Comparative Study of the Effects of Aflatoxin B$_1$ Metabolites and α-Amanitin on Rat Liver RNA Polymerase and Chromatin Template Activities.** (Eng) Prasanna, H. R. (Dept. Molecular Biology, State Univ. New York at Buffalo, Buffalo, NY); Gupta, S. R.; Viswanathan, L.; Venkitasubramanian, T. A. *Toxicon* 16(3): 289-294; 1978.

The effects of aflatoxin B_1 (AFB) metabolites on rat liver RNA polymerase and chromatin template activities were compared with those of α-amanitin. AFB was administered to male albino rats at a dose of 1 mg/kg ip, and the rats were sacrificed 4 hr later. Liver slices from these rats were treated with 3.12 μg/ml AFB or 0.1 μg/ml α-amanitin. Both compounds inhibited nucleoplasmic RNA synthesis but had very little effect on nucleolar RNA synthesis. AFB strongly suppressed RNA synthesis by liver nuclei in vitro, but had no effect on the protein content of the nuclear fraction. α-Amanitin strongly inhibited RNA synthesis by hepatic nuclei from control rats but had no effect on hepatic nuclei from AFB-treated rats. Addition of 0.001 μg α-amanitin in vitro inhibited RNA polymerase activity of control rats, but 0.01 μg inhibited enzyme activity of both control and treated rats. At low and high α-amanitin concentrations, enzyme activity was the same in control and treated rats, indicating that this compound did not exert an additive inhibitory effect on enzyme activity in AFB-treated rats. Further experiments indicated that AFB administration reduced RNA polymerase activity by 35% and the template activity of chromatin by 31%. When both enzyme and chromatin were obtained from treated rats, a 72% inhibition was observed, indicating that these two effects were additive. α-Amanitin inhibited RNA synthesis by preparations from control rats by 23%, but had no effect on preparations from treated rats. (21 refs)

78-4263 **Aflatoxin B_1 Induction of Hepatocellular Carcinoma in the Embryos of Rainbow Trout (*Salmo gairdneri*).** (Eng) Wales, J. H. (Dept. Food Science and Technology, Oregon State Univ., Corvallis, OR, 97331); Sinnhuber, R. O.; Hendricks, J. D.; Nixon, J. E.; Eisele, T. A. *J Natl Cancer Inst* 60(5): 1133-1139; 1978.

Liver cancer was induced in rainbow trout by the exposure of fertile eggs to an aqueous soln of aflatoxin B_1 (AFB_1: 0.5 μg/ml) for 1 hr. Single treatments, given on alternate days during the embryonic period, produced a low hepatocellular carcinoma incidence (< 20%) prior to formation of the embryonic liver on day 14, but a steadily increasing incidence from day 15 (31.7%) until day 23 (58.3%), in fish examined 1 yr later. Treatment of trout eggs with ^{14}C-AFB_1 was used to quantitate the amount of AFB_1 absorbed by the eggs. Trout eggs treated 21 days after fertilization absorbed approx 30 nanograms of ^{14}C-AFB_1 during a 1-hr exposure to 0.5 ppm aqueous ^{14}C-AFB_1. After 1 day, 85%-90% of the ^{14}C-AFB_1 was metabolized and excreted or it was leached from the egg. The residual ^{14}C-AFB_1 remained constant until hatching, when an additional 50% was lost. Comparison of the amount of AFB_1 absorbed by the eggs with the amount of AFB_1 consumed per fish during a 1-yr feeding trial (at 4 ppb in the diet) indicates that the trout embryo is even more sensitive than juvenile trout to the carcinogenicity of AFB_1. (12 refs)

78-4264 **Reduced Nicotinamide Adenine Dinucleotide Phosphate-dependent Formation of 2,3-Dihydro-2,3-dihydroxyaflatoxin B_1 from Aflatoxin B_1 by Hepatic Microsomes.** (Eng) Lin, J. K. (Dept. Biochemistry, Coll. Medicine, Natl. Taiwan Univ., Taipei, Taiwan, China); Kennan, K. A.; Miller, E. C.; Miller, J. A. *Cancer Res* 38(8): 2424-2428; 1978.

2,3-Dihydro-2,3-dihydroxyaflatoxin B_1 (AFB_1 dihydrodriol) was formed as a major metabolite during the incubation of AFB_1 with rat and hamster liver microsomes. The yield of the dihydrodiol was max at pH 6.5, and its formation was dependent on NADPH and cytochrome P-450. Phenobarbital pretreatment of the animals resulted in a two- to fourfold increase in dihydrodiol formation by liver microsomes. However, 3-methylcholanthrene pretreatment did not alter the activity of rat liver microsomes. Inhibitors of epoxide hydrase did not lower the dihydrodiol yield in these systems. Dihydrodiol formation from AFB_1 and rat liver microsomes was negligible in the presence of DNA. Little or no formation was noted with microsomes from rat intestinal mucosa, kidney, or lung. These results further support the formation of AFB_1 2,3-oxide as a major electrophilic metabolite of AFB_1 in rat and hamster liver microsomal systems, since this highly reactive epoxide would be expected to hydrolyze readily to form the dihydrodiol. (29 refs)

Environmental Medicine, New York Univ. Medical Center, New York, NY, 10016); Mate, U.; Wortman, M. *Proc Am Assoc Cancer Res* 19: 4; 1978. (no refs)

78-4266 **Mutagenicity of Inorganic Compounds in *Salmonella typhimurium*: Arsenic, Chromium and Selenium (Meeting Abstract).** (Eng) Lofroth, G. (Biochemistry Dept., Univ. California, Berkeley, CA, 94720); Ames, B. N. *Mutat Res* 53(1): 65-66; 1978. (no refs)

78-4267 **Metabolism of the Carcinogen Chromate by Rat Liver Microsomes.** (Eng) Gruber, J. E. (Dept. Chemistry, Dartmouth Coll., Hanover, NH, 03755); Jennette, K. W. *Biochem Biophys Res Commun* 82(2): 700-706; 1978.

The in vitro metabolism of chromate by rat liver microsomes was studied to determine whether the oxidation state of chromium would be affected. Incubation of chromate with rat liver microsomes and NADPH resulted in the reduction of hexavalent chromium to trivalent chromium, the amount of chromate reduced depending on the concentration of microsomes and NADPH. Max (complete) conversion to chromium(III) occurred with a microsome concentration of 1.5 mg/ml and an NADPH concentration of 1.44×10^{-3} M for 6 hr. Incubation of chromate with microsomes in the absence of NADPH led to complete recovery of chromate even after 24 hr incubation. In the absence of microsomes, $<20\%$ of the chromate was reduced by NADPH after 6 hr. These results suggest that an NADPH-requiring enzyme or enzyme system is involved in the in vitro metabolism of chromate. These data plus the results of earlier studies indicate that the metabolism of chromate by microsomal systems occurs in vitro and that it may be an important factor in determining the mutagenicity and carcinogenicity of chromium(VI) compounds in vivo. (16 refs.)

78-4268 **Cytogenetic Effects of Food Preservatives Sodium Sulphite and Sodium Benzoate (Meeting Abstract).** (Eng) Gopalan, H. N. (Botany Dept., Kenyatta Univ. Coll., Box 43844, Nairobi, Kenya); Njagi, G. D. *Genetics* 88(4, part 2, Suppl): s32-s33; 1978. (no refs)

78-4269 **Chromosomal Damage and Hair Dyes (2 Letters to Editor).** (Eng) Van Abbe, N. J. (British Industrial and Biological Res. Assoc., Carshalton, Surrey, England); Price, D. J. *Lancet* 2(8085): 368; 1978.

A three-way contingency analysis of the effect of hair dyes on chromosomes indicated that the damage associated with hair dyeing alone was not as prominent as that induced by high-dose radiography or the more serious viral infections. In another analysis of the data using the G-test, the excess chromosomal damage induced by dyes was found to be statistically significant, as was that induced by radiation and recent virus infections. However, there was no interaction between the dye and the other factors. (1 ref.)

78-4270 **Study of the Mutagenic Potential of Three GRAS Chemicals in Mice by the Heritable Translocation Test (Meeting Abstract).** (Eng) Jorgenson, T. A. (Stanford Res. Inst., Menlo Park, CA); Rushbrook, C. J.; Newell, G. W.; Green, S. *Mutat Res* 53(1): 124-125; 1978. (no refs)

78-4271 **Growth and Cytogenetic Characteristics of Nickel Sulphide-induced Rhabdomyosarcomas in Rats.** (Eng) Yamashiro, S. (Dept. Biomedical Sciences, Univ. Guelph, Guelph, Ontario, Canada N1G 2W1); Gilman, J. P.; Basrur, P. K.; Abandowitz, H. M. *Acta Pathol Jpn* 28(3): 435-444; 1978.

Rhabdomyosarcomas induced by single im injections of nickel sulfide (Ni_3S_2) in Fischer and Hooded rats were cultured in vivo and in vitro to study their growth characteristics and chromosome constitution. Tumor cell suspensions cultured in vitro exhibited more myogenic differentiation on the coverslips than cells grown in vivo in diffusion chambers. A characteristic feature of in vivo cultures was the appearance of microclusters that resembled the primary tumors. Chromosome analyses of the primary tumors revealed that a majority had a modal number in the diploid or near-diploid range. Fischer rat primary tumor cells exhibited abnormal configurations, including rings, dicentrics and triradials. A comparison of the chromosome makeup of the primary tumors and their metastases was performed on four sets of tumors. Three out of four metastases examined showed the diploid chromosome makeup characteristic of the primary tumors, suggesting that tumors with a diploid or near-diploid chromosome constitution are more likely to produce metastases. (19 refs)

78-4272 **Unscheduled DNA Synthesis Induced in Mouse Spermatids after Combined Treatment with Methyl Methanesulfonate and X-Rays.** (Eng) Carpenter, D. A. (Univ. Tennessee-Oak Ridge Graduate Sch. Biomedical Sciences, Oak Ridge, TN, 37830); Sega, G. A. *Mutat Res* 50(2): 219-228; 1978.

The combined effects of methyl methanesulfonate (MMS) and x-rays on (C3Hf x 101)F_1 mouse spermatids were determined. Mice were given 75 mg/kg MMS ip and a concurrent testicular injection of ^{3}H-thymidine (^{3}H-TdR) either immediately before or up to 20 hr after x-ray treatment (50-600 R). X-rays and MMS induced unscheduled DNA synthesis (UDS) in the spermatids. However, there was a statistically significant reduction in the amount of UDS when x-ray exposures of 200-600 R were given 4 hr before the MMS + (^{3}H)dThd injection. This reduction was greater than that which could be explained by the completion of repair of x-ray-induced lesions. It is suggested that the reduction in UDS was the result of an x-ray-produced impairment of at least a part of the repair mechanism involved in correcting MMS-induced DNA lesions. When the time interval between a 600-R x-ray exposure and MMS treatment was between 3 and 20 hr, there was a statistically significant reduction in UDS in the spermatids. No significant decrease in the UDS response occurred when the time interval between radiation expsure and MMS treatment was approx $<$ 3 hr. (10 refs)

78-4273 **The Metabolism of Lithocholic Acid-3α-sulfate by Human Intestinal Microflora.** (Eng) Kelsey,

M. I. (Chemical Carcinogenesis Program, NCI Frederick Cancer Res. Center, P.O. Box B, Frederick, MD, 21501); Muschik, G. M.; Sexton, S. A. *Lipids* 13(2): 152-157; 1978.

Human intestinal microflora from freshly collected human feces were incubated with lithocholic acid 3α-sulfate, and the metabolites were analyzed by chromatography and mass spectrometry. The chromatographic properties of one of the metabolites were consistent with those described for a Δ^2- or Δ^3-cholenate. The formation of cholenates by the microflora may represent a retoxification of the sulfate ester of lithocholic acid. Since the compound is a major bile salt in the colon, microbial metabolism of this substrate may result in toxic or mutagenic products in patients at risk for colon cancer. (29 refs)

78-4274 **Malignant Mesothelioma with Minimal Asbestos Exposure.** (Eng) Chen, W. (Dept. Pathology, Univ. Washington Sch. Medicine, Seattle, WA, 98195); Mottet, N. K. *Hum Pathol* 9(3): 253-258; 1978.

The occurrence of a malignant mesothelioma in a 59-yr-old nonsmoker with minimal asbestos exposure is reported. The extent of exposure was documented by thorough examination of the patient's occupational history and personal hobbies and by counting the number of asbestos fibers in the lungs. There was an av of 168 fibers per 5 g wet tissue sample. Electron probe x-ray dispersion analysis of the fibers revealed the characteristic chemical components of asbestos – Si, Mg, Ca, and Fe. (16 refs)

78-4275 **Colon Cancer, Bile-Salt Binding, and Aluminium Hydroxide (Letter to Editor).** (Eng) Cruse, J. P. (Surgical Unit, Rayne Inst., Univ. Coll. Hosp. Medical Sch., London WC1E 6JJ, England); Lewin, M. R.; Clark, C. G. *Lancet* 1(8076): 1261; 1978.

The antacid aluminum hydroxide (AH), a bile salt-binding compound, may indirectly promote colon cancer by increasing the delivery of bile salts to the large intestine. A study of dimethylhydrazine-treated Wistar rats showed that AH increased the mortality over that due to the carcinogen alone. AH may be harmful to patients who have, or have had, carcinoma of the colon. (9 refs)

78-4276 **DNA Alkylation in Mice with Genetically Different Susceptibility to 1,2-Dimethylhydrazine-induced Colon Carcinogenesis.** (Eng) Cooper, H. K. (Abteilung Chemie, Ruhr-Universitat, 4630 Bochum, W. Germany); Buecheler, J.; Kleihues, P. *Cancer Res* 38(9): 3063-3065; 1978.

The role of methylation of DNA bases in the initiation of colon tumors by 1,2-dimethylhydrazine (DMH) was studied in male mice with a high (ICR/Ha) and low (C57BL/Ha) susceptibility to DMH-induced colon carcinogenesis. The mice were given a single sc injection of 15 mg/kg ^{14}C-DMH and sacrificed either 12 or 60 hr later. The concentrations of 7-methylguanine and O^6-methylguanine in the DNA of the colon, ileum, and kidney were 40%-60% lower in C57BL/Ha mice than in ICR/Ha mice. In hepatic DNA, the extent of methylation was higher in C57BL/Ha than in ICR/Ha mice. The rate of loss of methylated purines from colon DNA was similar in both strains. In all organs investigated, the incorporation of label into normal DNA bases was lower in C57BL/Ha mice. It was concluded that the low carcinogenic response of C57BL/Ha mice was due to the smaller extent of initial alkylation of colon DNA, which probably reflects differences in the enzymic metabolism of the parent carcinogen. (17 refs.)

78-4277 **DNA Damage in Liver, Colon, Stomach, Lung and Kidney of BALB/c Mice Treated with 1,2-Dimethylhydrazine.** (Eng) Brambilla, G. (Dept. Pharmacology, Univ. Genoa, I-16132 Genoa, Italy); Cavanna, M.; Parodi, S.; Sciaba, L.; Pino, A.; Robbiano, L. *Int J Cancer* 22(2): 174-180; 1978.

DNA single-strand breaks induced in various organs of BALB/c mice by treatment with a single dose of 1,2-dimethylhydrazine [DMH: 12.5-200 mg/kg were studied po (gastric intubation) or sc] were studied by a modified alkaline elution method. The modification allowed the evaluation of DNA damage in vivo without the use of radioactive prelabeling; DNA damage was detected in liver, lung, kidney, stomach and colon mucosa, with the liver showing the greatest amount of damage. The degree of damage was dependent on the dose and route of administration, being greater by the sc route. A differential effect was evident in colon mucosa from Swiss and C57BL/6 mice, which are respectively susceptible and resistant to the induction of bowel tumors by DMH. The higher degree of DNA damage found in liver in comparison with colon mucosa is consistent with the previously reported higher degree of DNA methylation in the former, but it does not correlate with the specificity of this carcinogen in inducing large intestinal tumors in mice given repeated sc injections. (62 refs.)

78-4278 **The Influence of Serotonin on the Mitotic Rate in the Colonic Crypt Epithelium and in Colonic Adenocarcinoma in Rats.** (Eng) Tutton, P. J. (Dept. Anatomy, Monash Univ., Clayton, Victoria, Australia); Barkla, D. H. *Clin Exp Pharmacol Physiol* 5(1): 91-94; 1978.

The influence of serotonin on the mitotic rate in colonic crypt epithelium and in chemically induced colonic adenocarcinomas was studied in male Sprague-Dawley rats. The rats were given 21 weekly injections of 1,2-dimethylhydrazine (21 mg/kg, sc) and then studied 2-8 wk later. In animals partially depleted of serotonin following an injection of 6-fluorotryptophan and in those whose serotonin receptors were blocked by treatment with bromolysergic acid diethylamide, cell proliferation proceeded at a normal rate in the crypt epithelium while essentially ceasing in the colonic tumors. Injection of 10 μg/kg serotonin caused an increase in the mitotic rate in the tumor tissue but not in the crypt epithelium. Blocking α-adrenoreceptors, while simultaneously stimulating serotonin receptors, might, by transiently decreasing the ratio between cell proliferation rates in normal and neoplastic cells, increase the efficacy of antineoplastic drugs whose specificity is for rapidly dividing cells. (14 refs)

78-4279 **Evidence of DNA Repair in the Guinea Pig Pancreas, In Vivo and In Vitro, Following Exposure to N-Methyl-N-Nitrosourethane.** (Eng) Iqbal, Z. M. (Sch. Public Health, Univ. Illinois Medical Center, P.O. Box 6998, Chicago, IL, 60680); Epstein, S. S. *Chem Biol Interact* 20(1): 77-87; 1978.

The DNA damage induced by N-methyl-N-nitrosourethane (NMUT) in the guinea pig pancreas and its subsequent repair was investigated in vitro and in vivo by alkaline sucrose density gradient analysis. A nonradioactive fluorimetric procedure was used to determine the DNA in gradient fractions. Following 30 min in vitro exposure of pancreatic slices to 20 mM NMUT, 65.5% of the DNA sedimented near the top of the gradient as $< 2.24 \times 10^6$-dalton fragments. However, incubation of carcinogen-treated slices for 3 hr in a fresh medium resulted in the repair of most DNA damage, as indicated by conversion of the low-mol-wt DNA fragments to DNA of mol wt comparable to that of control slices. A single ip administration of NMUT (30 mg/kg) to guinea pigs also induced extensive DNA damage ($< 2.24\ 10^6$-dalton fragments) in the pancreas within 4 hr; similar DNA damage was observed in the liver. However, in the pancreas and liver of animals sacrificed at increasing intervals after NMUT administration, a gradual conversion of shortened DNA fragments to high-mol-wt DNA indicated repair of DNA damage. Most of the DNA damage in the pancreas and liver was repaired by 14 and 7 days, respectively. (24 refs)

78-4280 **Mutagenicity Testing of Benomyl, Methyl-2-benzimidazole Carbamate, Streptozotocin and N-Methyl-N′-nitro-N-nitrosoguanidine in *Salmonella typhimurium* In Vitro and in Rodent Host-mediated Assays.** (Eng) Ficsor, G. (Dept. Biomedical Sciences, Western Michigan Univ., Kalamazoo, MI); Bordas, S.; Stewart, S. J. *Mutat Res* 51(2): 151-164; 1978.

In vitro spot tests, microsomal plate assays, liquid culture treatments, and rodent host-mediated assays were used to test the mutagenicity of benomyl, its commercial preparations Fundazol 50WP and Benlate 50WP, the benomyl metabolite methyl-2-benzimidazole carbamate (MBC), and its commercial preparation MBC 50WP. *Salmonella typhimurium* strains *his*G46, TA100, TA1530, TA1535 and TA1950 were used. In nonoverlay spot tests, Benlate 50WP was nonmutagenic to *his*G46 and TA1535 over a dose range of 50-5,000 θg/spot. In overlay spot tests of all five compounds (50-100 μg/spot) with *his*G46, TA1530, and TA1950, only MBC (100 μg/spot) showed weak mutagenicity in *his*G46. Positive controls were mutagenic in each strain. Toxicity was not observed. In the microsomal activation plate assay, MBC, benomyl, Fundazol 50WP and Benlate 50WP (50-2,000 μg/plate) were tested with TA100, and all were found to be nonmutagenic. Fundazol 50WP (10, 100, 1,000, and 10,000 μg/ml) was nonmutagenic to TA1530 in a 20 hr liquid culture treatment. In 1-hr liquid culture treatments, benomyl, Benlate 50WP, and Fundazol 50WP (0.25-1,000 μg/ml) failed to produce mutation in *his*G46, TA100 or TA1950. Appropriate positive controls were mutagenic in each test. In the rodent host-mediated assay, Fundazol 50WP was not mutagenic in mice [sc (500 mg/kg at 0, 1, 2 hr) with *his*G46 or po (4000 mg) with TA1950] but the positive control streptozotocin was. The consistently negative results in this study with commercial preparations of MBC and benomyl are contrary to positive findings reported previously with similar methods and similar preparations. Possible reasons for these differences are presented. (14 refs.)

78-4281 **Comparisons of the Fidelity of Transcription of RNA Polymerase I and II Following N-Hydroxy-2-acetylaminofluorene Treatment.** (Eng) Glazer, R. I. (Lab. Medicinal Chemistry and Biology, NCI, Room 6A01, Building 37, Bethesda, MD, 20014). *Nucleic Acids Res* 5(7): 2607-2616; 1978.

An attempt was made to determine if misincorporation is responsible for changes in the nucleotide distribution of the RNA transcribed by carcinogen-modified enzymes. Hepatic RNA polymerase I and II from normal or N-2-hydroxy-2-acetylaminofluorene (OH-AAF)-treated Sprague-Dawley rats or *Escherichia coli* polymerase and the synthetic templates poly(dG-dC)-poly(dG-dC) (A) and poly(dA-dT)-poly(dA-dT) (B) were used With template A, the predominant base-pair transformation that was transcribed in the presence of $Mg+^{2}$ or $Mn+^{2}$ by RNA polymerase I from control or OH-AAF-treated animals or by *E. coli* RNA polymerase was the transversion dG-rC to dG-rA. However, transcription in the presence of $Mg+^{2}$ by RN polymerase II from carcinogen-treated animals showed a statistically greater degree of the base-pair transformation dG-rC to dG-rU. In contrast, RNA polymerase I and II from control or OH-AAF-treated rats transcribed the base-pair transformation dA-rU to dA-rG, dA-rU to dA-rC, and dA-rU to dA-rA to equal extents with template B. *E. coli* RNA polymerase transcribed template B to produce only the transversion dA-rU to dA-rG. The results show that there is an inherently high degree of misincorporation by both rat liver enzymes and the bacterial polymerase when transcribing template A, compared with the low error rate that occurs with template B. Thus, RNA polymerases are capable of miscopying synthetic DNA templates. The consequences of base-pair transformations on the fidelity of transcription after carcinogen treatment are explored. (21 refs.)

78-4282 **Photolysis of 2-Azidofluorene In Situ as a Probe in Chemical Carcinogenesis: Bypass of Requirement for Metabolic Activation.** (Eng) Sarrif, A. M. (Dept. Pharmacology, Univ. Alabama in Birmingham Medical Center, Birmingham, AL, 35294); White, W. E.; DiVito, N. *Biochem Biophys Res Commun* 83(2): 506-512; 1978.

Photoaffinity labeling was used as a probe for studying carcinogenesis in C3H 10T1/2 CL8 mouse embryo fibroblasts. 2-Azidofluorene (2-AzF) was synthesized to serve as a specific photoaffinity label. Nonirradiated 2-AzF exhibited little toxicity and no transforming activity in the C3H cells. When 2-AzF was photolyzed by UV light (360 nanometers) in water to generate N-hydroxy-2-aminofluorene and then added to the cell, little toxicity again was noted, but the drug was weakly transforming. In both experiments, cell survival was 75%. However, when 2-AzF was incubated with the cells for 10 min and then photolyzed for 15 min, cell survival was reduced to 11%. The drug plus UV light also caused significant transformation, with both Types II and III foci being observed. The cytotoxicity profile and the amount of transformation induced were comparable with those obtained with N-acetoxy-2-acetylaminofluorene. Irradiation of the cells in the absence of the drug was virtually nontoxic and nontransforming. These findings indicate that photoaffinity labeling may be used as a specific probe in cell transformation studies. (13 refs.)

78-4283 **Effects of Acetylaminofluorene on Transfer RNA Methyltransferases of Rat Organs.** (Eng) Wainfan, E. (Lindsley F. Kimball Res. Inst. New York Blood Center, New York, NY); Randle, S. S.; Relyea, N. M.; Balis, M. E. *Cancer Res* 38(7): 1852-1856; 1978.

The activity of transfer RNA (tRNA) methyltransferases and levels of polyamines in the liver and other organs were measured in male and female CFN rats during the administration of acetylaminofluorene (AAF, 0.06% in the diet). Both the specific activity and max capacity of the tRNA-methylating enzymes in male rats that had received AAF for 3 wk were about double control levels. When HN_4+ was added to the assay mixture, there was an almost three-fold stimulation of enzyme activity in both groups. In AAF-treated males, the activity of liver tRNA methylase rose sharply within 5 days and remained elevated. In the treated females, liver tRNA methylase activity was only slightly increased after 5 days and was within control limits after 3 wk. There were no sex-related differences in enzyme activity in the controls. The increased enzyme activity in the males was still evident after 3 and 6 mo of AAF treatment. The tRNA-methylating enzyme activities in the spleen and colonic mucosal cells of treated males did not differ significantly from control levels. No significant differences in liver polyamine levels were observed between treated males and controls. These findings suggest that there may be a correlation between AAF-induced qualitative and quantitative changes in tRNA methylase activity and the initiation of steps leading to neoplasia. (no refs.)

78-4284 **Identification of Epoxide Hydrase as the Preneoplastic Antigen in Rat Liver Hyperplastic Nodules.** (Eng) Levin, W. (Dept. Biochemistry and Drug Metabolism, Hoffmann-La Roche Inc., Nutley, NJ, 07110); Lu, A. Y.; Thomas, P. E.; Ryan, D.; Kizer, D. E.; Griffin, M. J. *Proc Natl Acad Sci USA* 75(7): 3240-3243; 1978.

A liver microsomal protein, termed preneoplastic antigen, was detected in the hyperplastic nodules of male Holtzman rats fed a diet containing 2-acetylaminofluorene and was identified as the enzyme epoxide hydrase [glycol hydro-lyase (epoxide-forming)]. Purified preneoplastic antigen from hyperplastic nodules and purified rat liver microsomal epoxide hydrase were immunochemically identical on the basis of Ouchterlony double-diffusion analysis. In addition, the purified proteins had identical minimum mol wts in sodium dodecyl sulfate/polyacrylamide gels and both catalyzed the hydration of arene oxides to dihydrodiols. Chronic feeding of 2-acetylaminofluorene (0.05% of diet) to rats resulted in a five- to sevenfold increase in epoxide hydrase activity in the liver. The induced level of the enzyme was maintained in developing hyperplastic nodules and hepatomas, but not in the nontumor tissue after the carcinogen was removed from the diet. (24 refs.)

78-4285 **Unscheduled DNA Synthesis Induced by Procarcinogens in Suspensions and Primary Cultures of Hepatocytes on Collagen Membranes.** (Eng) Michalopoulos, G. (Jones Lab. Cancer Res., Dept. Pathology, Duke Univ. Medical Center, Durham, NC, 27710); Sattler, G. L.; O'Connor, L.; Pitot, H. C. *Cancer Res* 38(7): 1866-1871; 1978.

The feasibility of using suspensions of freshly isolated hepatocytes as a system for the rapid in vitro detection of potential chemical carcinogens was studied. The amounts of unscheduled DNA synthesis (UDS) in hepatocellular suspensions were measured after isolation of the DNA by two methods. With the trichloroacetic acid (TCA) precipitation method, insignificant (10%-20%) UDS was observed when high concentrations of the procarcinogen N-2-fluorenylacetamide (AAF) were used. When the cell DNA was isolated on cesium chloride gradients, much higher levels of UDS were measured at the same AAF concentrations. Suspensions of freshly isolated hepatocytes were incubated with various procarcinogens and ^{3}H-thymidine, and the DNA was isolated on cesium chloride gradients. Dimethylnitrosamine (DMN) elicited measureable UDS at high concentrations. 3′-Methyl-4-dimethylaminoazobenzene (3′MeDAB) also elicited measurable UDS at 2×10^{-5} M, but higher concentrations resulted in less UDS, possibly because of the toxicity of the compound. Similar toxicity effects were seen with benzo(a)pyrene (BP), which elicited max UDS at 8×10^{-6} M. UDS increased with increasing AAF concentration and with increasing aflatoxin B_1 concentration up to 10^{-6} M. Of the five carcinogens tested, BP and aflatoxin were the most effective in eliciting UDS. BP was also the most effective in eliciting UDS in 6-day-old cultures of hepatocytes on collagen membranes. UDS caused by the addition of AAF, 3′MeDAB, and aflatoxin B_1 to these cultures was less than that observed with similar concentrations of these carcinogens in suspensions of freshly isolated hepatocytes. (23 refs.)

78-4286 **Different Deviation Patterns of Carbohydrate-metabolizing Enzymes in Primary Rat Hepatomas Induced by Different Chemical Carcinogens.** (Eng) Sato, K. (Second Dept. Biochemistry, Hirosaki Univ. Sch. Medicine, Hirosaki 036, Japan); Takaya, S.; Imai, F.; Hatayama, I.; Ito, N. *Cancer Res* 38(9): 3086-3093; 1978.

The deviation patterns of nine carbohydrate metabolizing enzymes were examined simultaneously in the individual hyperplastic liver nodules and primary hepatomas induced in Sprague-Dawley rats by N-2-fluorenylacetamide (2-FAA), diethylnitrosamine (DENA), or 3′-methyl-4-dimethylaminoazobenzene (3′-Me-DAB). Rats were fed a diet containing 0.025% 2-FAA for 20 wk and then a normal diet for 4-12 wk, or 0.01% DENA in the drinking water for 3 wk, or a diet containing 0.06% 3′-Me-DAB for 25-29 wk. With decreased histological differentiation of the tumor, the liver-specific marker enzymes of gluconeogenesis, glucose-6-phosphatase and fructose-1,6-bis-phosphatase, as well as the hepatic isozymes of glucose-adenosine 5′-triphosphate phosphotransferase (GATP), pyruvate kinase, aldolase, and glycogen phosphorylase, decreased gradually and were replaced with the respective nonhepatic fetal or prototypic isozymes of undifferentiated tissues. In poorly differentiated hepatomas, glycogen synthase was also decreased and phosphofructokinase was increased. Glucose-6-phosphate dehydrogenase increased remarkably from nodular hyperplasia with no relation to differentiation. The degree of enzyme deviation from adult male liver differed among hepatomas induced by the different carcinogens, especially between those induced by 2-FAA and 3′-Me-DAB. These differences were most evident in the isozyme deviation patterns of GATP and pyruvate kinase. Some of the nodules and hepatomas retained exceptionally high activities of some hepatic isozymes, especially of the liver type of pyruvate kinase. These findings indicate that the enzyme deviation patterns in the hyperplastic liver nodules and primary hepatomas are similar to those found in transplantable hepatomas. (50 refs.)

78-4287 **Aldehyde Dehydrogenase in 2-Acetylaminofluorene-induced Rat Hepatomas. Characterization of Antigens Recognized by Anti-hepatoma Aldehyde Dehydrogenase Sera.** (Eng) Lindahl, R. (Developmental Biology Section, Dept. Biology, Univ. Alabama, University, AL, 35486). *Biochim Biophys Acta* 525(1): 9-17; 1978.

The material in normal rat liver that cross-reacts with anti-hepatoma aldehyde dehydrogenase (ADH) sera has been partially purified. This material is a series of proteins electrophoretically identical to the series of hepatoma-specific ADH's [aldehyde:NAD(P)+ oxidoreductase] induced by 2-acetylaminofluorene. The mol wts (100,000) and the isoelectric points (pI: 6.8-7.2) of the cross-reacting material are identical to the mol wts and p values of the hepatoma-specific isozymes. Absorption of anti-hepatoma ADH sera with the cross-reacting material removes an antibody population that recognizes a normal liver ADH. This isozyme accounts for 35% of the total normal liver ADH. A second antibody population recognizes an antigen that accounts for 10% of the total normal liver ADH. Approx 55% of the normal liver ADH activity is not recognized by any antibody population. In hepatomas, 15% of the total ADH activity is immunochemically identical to the normal liver cross-reacting material. The remaining 85% of the tumor ADH is characterizable as hepatoma-specific on the basis of these immunochemical studies. (12 refs.)

78-4288 **Mutagenic Activation of N-Hydroxy-2-acetylaminofluorene in the *Salmonella* Test System: The Role of Deacetylation by Liver and Kidney Fractions from Mouse and Rat.** (Eng) Schut, H. A. (Biochemical Pharmacology Section, Lab. Chemical Pharmacology, Developmental Therapeutics Program, Div. Cancer Treatment, NCI, NIH, Bethesda, MD, 20014); Wirth, P. J.; Thorgeirsson, S. S. *Mol Pharmacol* 14(4): 682-692; 1978.

An attempt was made to relate liver (L) and kidney (K) microsomal deacetylases, and their possible induction, to the mutagenic activation of N-hydroxy-2-acetylaminofluorene (OH-AAF) in vitro, using C57BL/6N and DBA/2N mice and Sprague-Dawley rats and the Salmonella (strain TA1538) mutagenesis assay. The mutagenicity of OH-AAF mediated by L or K microsomes was independent of treatment of mice or rats with microsomal enzyme inducers (3-methylcholanthrene, phenobarbital, Arochlor) and, at equivalent protein concentrations, was the same whether mouse L or mouse K microsomes were used. Mutagenesis with L or K microsomes from both species was inhibited completely by 0.1 mM paraoxon and partially by 3′-phosphoadenosine 5′-phosphosulfate (25-75 times the molar concentration of OH-AAF) when the rat $< 9{,}000 \times g$ supernatant was used. Although the rates of deacetylation of 2-acetylaminofluorene and OH-AAF were lower in K microsomes than in L microsomes of either species, both reactions were also inhibited completely by paraoxon. Ascorbic acid (10 mM) approx doubled the mutagenicity of OH-AAF in the presence of mouse K microsomes, but it had no effect in their absence. Butylated hydroxytoluene (10 mM) had very little or no effect, with or without ascorbic acid, on OH-AAF mutagenicity in the presence of L or K microsomes. It is concluded that in L and K fractions from the mouse and rat, the most important enzymatic step in the metabolic activation of OH-AAF to a mutagen in the Salmonella test system is deacetylation. Apparently, the OH-AAF-derived nitrenium ion, rather than the nitroxyl free radical, is the more important electrophilic species interacting with the bacterial DNA, resulting in frameshift mutations. (46 refs.)

78-4289 **Mutagenesis by N-Acetoxy-2-acetyl Aminofluorene of Chinese Hamster V79 Cells is Unaffected by Caffeine.** (Eng) Myhr, B. C. (Biology Branch, Somatic Cell Genetics Section, NCI, Bethesda, MD, 20014); DiPaolo, J. A. *Chem Biol Interact* 21(1): 1-18; 1978.

The effect of caffeine (CF) on the mutagenicity of N-acetoxy-2-acetylaminofluorene (AcAAF) was determined in Chinese hamster V79 cells using a reseeding assay in which the cells were reseeded prior to selection to achieve max expression without interference from metabolic crossfeeding. An in situ assay was also used for comparison. AcAAF (0.1-2.5 μg/ml) induced 8-azaguanine (AZG)- and 6-thioguanine (TG)-resistant cells in clone V79-4 cells in the presence of 5% fetal bovine serum. The number of mutants increased from 1 to $47/10^5$ survivors at 55-130 hr after treatment. The effect of CF (50-200 μg/ml) on mutation frequency was determined by adding CF 1-24 hr after AcAAF. The medium was replaced after 48 hr so that CF was absent during subsequent selection with AZG or TG. There was no significant change in AcAAF mutagenesis with any treatment combination, although CF greatly enhanced the lethality of AcAAF. CF appears to inhibit a postreplication repair process in the V79-4 cells, causing potentiation of AcAAF lethality without altering the error probability of the remaining postreplication repair activity. The in situ assay was subject to serious interference from crossfeeding, and it yielded an artifactual tenfold enhancement of AcAAF mutagenesis by CF. (32 refs)

78-4290 **A Comparative Study of Cyclophosphamide Using In Vivo and In Vitro Metabolic Activating Systems and *Salmonella typhimurium* Indicators** (Meeting Abstract). (Eng) Steelman, J. R. (McNeil Lab., Inc., Fort Washington, PA, 19034); Schreiner, C. A. *Mutat Res* 53(1): 72-73; 1978. (no refs)

78-4291 **Testing In Vitro of an Indirect Mutagen (Cyclophosphamide) with Human Leukocyte Cultures. Activation by Liver Perfusion and by Incubation with Crude Liver Homogenate.** (Eng) Madle, S. (Institut fur Genetik, Freie Universitat Berlin, Arnimallee 5-7, 1000 Berlin 33, W. Germany); Westphal, D.; Hilbig, V.; Obe, G. *Mutat Res* 54(1): 95-99; 1978.

Two possible methods for activating cyclophosphamide (CP) and testing its mutagenicity in human WBC in vitro are reported: (1) perfusion of rat liver in situ with CP and direct addition of the perfusate to human whole blood cultures and (2) activation of CP with a crude homogenate of mouse liver and addition of the mixture to the cultures by means of dialysis bags. Male Wistar rat livers were perfused with 0.63-20 mM CP for 5 min or 1 hr. Blood cultures (2.5 ml) were incubated for 80 hr (including an 8-hr colcemid treatment), treated with 1 ml perfusate for 3 hr, and allowed to recover for 29 hr. The final CP concentration in the cultures was 0.18-5.71 mM. The perfusate led to a dose-dependent suppression of the mitotic index and to the induction of chromatid translocations. The results were similar regardless of perfusion time, indicating that the metabolic transformation of CP was completed in 5 min or that a steady state was reached between the formation of chromosome-breaking products and their decomposition. In the second method, crude liver homogenates were obtained from phenobarbital-treated female NMRI mice. The homogenates were tested with and without 5 mM NADP and 10 mM glucose 6-phosphate. CP (0.16-20 mM) was added, 1 ml of the mixture was put into a dialysis bag, and the bag was submersed in colcemid-treated cultures for 3 hr at incubation hours 48-51. The final CP concentration was 0.05-5.71 mM. The results were similar to those of the perfusion experiments, except that the effects of the liver homogenates without cofactors were weaker. Mitotic indices were suppressed only at 10 and 20 mM CP, and chromatid translocations were induced only at 20 mM. (8 refs)

78-4292 **Carcinogenic Action of Low-Dose Cyclophosphamide (CP) in Rats (Meeting Abstract).** (Eng) Habs, M. (Inst. Toxicology and Chemotherapy, German Cancer Res. Center, Im Neuenheimer Feld 280, 69 Heidelberg, W. Germany); Schmahl, D. *Proc Am Assoc Cancer Res* 19: 14; 1978. (no refs)

78-4293 **Azaserine Induced Damage in DNA of Cultured Rat Pancreas (Meeting Abstract).** (Eng) Lilja, H. S. (Dartmouth Medical Sch., Hanover, NH, 03755); Kuhlmann, E. T.; Yager, J. D.; Longnecker, D. S. *Proc Am Assoc Cancer Res* 19: 174; 1978. (1 ref)

78-4294 **Acute Leukemia after Chemotherapy (Melphalan).** (Eng) Einhorn, N. (Dept. Gynecological Oncology, Radiumhemmet Karolinska Hosp. and Inst., Stockholm 60, Sweden). *Cancer* 41(2): 444-447; 1978.

The incidence of acute leukemia was investigated in 48 patients who were seen between 1966-1973, who received a minimum of 300 mg melphalan, and who survived at least 3 yr. Eleven of the patients had received melphalan only, 2 also had received other cytostatic agents, 30 also had been irradiated, and 5 had received melphalan, other cytostatics, and irradiation. The melphalan was usually given iv at a dose of 1 mg/kg. Of the 48, 4 developed acute leukemia 3-6.5 yr after initiation of treatment; no other new primary malignant tumors were noted. One of the four had also received cyclophosphamide, and one had also been irradiated. The 4 patients were among the 12 who had received at least 800 mg melphalan. Case reports of the four women are presented. It is suggested that if the melphalan did cause the leukemia, the latency period was remarkably short. In the evaluation of chemotherapy as adjuvant treatment, the risk of developing new primary tumors must be considered. (11 refs)

78-4295 **Levodopa Therapy and Malignant Melanoma.** (Eng) Sober, A. J. (Dept. Dermatology, Massachusetts General Hosp., Boston, MA, 02114); Wick, M. M. *JAMA* 240(6): 554-555; 1978.

A questionnaire/interview study was conducted to determine whether levodopa (L-3,4-dihydroxyphenylalanine) is involved in the induction or stimulation of growth of cutaneous malignant melanoma. Prospective query of 1,099 patients of the Melanoma Clinical Cooperative Group at the time of presentation of their primary melanoma showed only 1 patient who had been taking levodopa. It was concluded that if levodopa is a factor in the induction of melanoma, it must be playing an inconsequential role in the rapid rise in incidence observed for this tumor over the past decade. (13 refs.)

78-4296 **High Levels of Reduced Glutathione in Glandular Rat Stomach; Possible Implications for Gastric Carcinogenesis (Meeting Abstract).** (Eng) Boyd, S. (Field Studies and Statistics, NCI, Bethesda, MD, 20014); Sasame, H. *Proc Am Assoc Cancer Res* 19: 121; 1978. (1 ref)

78-4297 **Determination of N-Nitrosamines in Water by Fluorescent Derivatives.** (Rus) Melamed, D. B. (Inst. Nutrition, Moscow, USSR); Kostiukoskii, Ia. L. *Gig Sanit* (5): 67-68; 1978.

A sensitive assay for determining the fluorescent derivatives of various N-nitrosamines in water is described. The derivatives were separated by thin-layer chromatography. The detection limit of the technique was 1 μg/liter. (3 refs)

78-4298 **Mutagenicity of Dimethylnitrosamine and Ethyl Methanesulfonate as Determined by the Host-Mediated CHO/HGPRT Assay.** (Eng) Hsie, A. W. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Machanoff, R.; Couch, D. B.; Holland, J. M. *Mutat Res* 51(1): 77-84; 1978.

The mutagenicity of the procarcinogen dimethylnitrosamine (DMN) was compared with that of the direct-acting alkylating agent ethyl methanesulfonate (EMS) using the host (mouse)-mediated Chinese hamster ovary/hypoxanthine-guanine phosphoribosyltransferase assay system. Both nude (athymic) and phenotypically normal BALB/c mice were used in the assays. The induced mutation frequency increased linearly with DMN dose up to 250 mg/kg using a 2-hr treatment time. For DMN doses of 100 and 500 mg/kg, the induced mutation frequency rose linearly with time up to 6 hr and continued to increase when cells were left in the peritoneal cavity for an additional 18 hr. DMN was not mutagenic when tested in vitro, but EMS-induced mutations increased in a time- and dose-dependent fashion both in vitro and in the host-mediated assay. (20 refs.)

78-4299 **Removal of Methylated Purines from Rat Liver DNA after Administration of Dimethylnitrosamine.** (Eng) Pegg, A. E. (Dept. Physiology, Milton S. Hershey Medical Center, Hershey, PA, 17033); Hui, G. *Cancer Res* 38(7): 2011-2017; 1978.

The removal of abnormal methylated purines induced by ip injection of various doses of dimethylnitrosamine (DMN) from female Sprague-Dawley rat liver DNA was investigated. All methylated purines formed in the DNA were lost to some extent over a 24-hr period, but the rate of removal varied from purine to purine. The rates of loss of 1-methyladenine, 3-methyladenine, 7-methyladenine, 3-methylguanine, and 7-methylguanine (7-MG) were not changed significantly when the extent of methylation was increased $>$20-fold by increasing the dose of DMN from 0.75 to 20 mg/kg. However, O^6-methylguanine (O^6-MG) was lost rapidly from the DNA after the lower DMN dose, but at a much slower rate after the higher dose. When chromatin was prepared from livers of rats treated with labeled DMN and partially digested with DNase I or micrococcal I or micrococcal nuclease, no difference in the level of 7-MG or O^6-MG between the nuclease-resistant and nuclease-sensitive portions of the chromatin DNA was seen. Changing the dose of DMN from 25 μg/kg to 20 mg/kg did not alter the relative distribution of these methylated guanines. Although a substantial amount of O^6-MG was lost from the chromatin DNA within 24 hr at the lower doses, there was no indication that this purine was lost more readily from either fraction of the chromatin DNA. When labeled O^6-MG, produced in hepatic DNA by administration of 0.75 mg/kg ^{14}C-DMN, was diluted by unlabeled O^6-MG, formed by a 20-mg/kg DMN dose given 1 hr later, the rate of loss of labeled O^6-MG was greatly reduced. It was concluded that O^6-MG is removed from hepatic DNA by a mechanism that is more efficient after lower DMN doses either because the removal system becomes saturated at higher levels of DNA methylation or because it is inhibited by he larger doses of this carcinogen. (49 refs)

78-4300 ***In Vivo* Reaction of Dimethylnitrosamine with Nucleic Acids.** (Eng) Grilli, S. (Istituto di Cancerologia, Universita degli Studi di Bologna, via S. Giacomo 14, 40126 Bologna, Italy); De Giovanni, C.; Prodi, G.; Giamanini, A. G. *Gann* 69(1): 39-45; 1978.

The in vivo reaction of dimethylnitrosamine (DMNA) with nucleic acids was studied to determine whether the methylamine nitrogen formed was derived from the DMNA. ^{14}C-^{15}N-DMNA (30 mg/kg) was injected ip into female Wistar rats, and the animals were killed 12 hr later. Their livers were extracted and pooled; DNA, ribosomal RNA, nuclear proteins, and cytoplasmic proteins were extracted; and the amount of radioactivity bound to the macromolecules was measured. Following strong acid hydrolysis, 7-methylguanine was the main compound resulting from the interaction of DMNA with the nucleic acids. Enzymatic and alkaline hydrolysis, however, resulted in the quantitative liberation of methylamine. Methylamine isolated from the liver nucleic acids of ^{15}N-DMNA-treated rats had a mol wt of 31, indicating that DMNA nitrogen is not involved in the binding. Since methylamine nitrogen cannot be derived from 7-methylguanosine fission, these findings disagree with the generally proposed mechanism of alkylation. (16 refs)

78-4301 **Urinary Excretion of N-Nitrosodiethanolamine Administered Orally to Rats.** (Eng) Preussmann, R. (Inst. Toxicology and Chemotherapy, German Cancer Res. Center, D-6900 Heidelberg, W. Germany); Wurtele, G.; Eisenbrand, G.; Spiegelhalder, B. *Cancer Lett* 4(4): 207-209; 1978.

N-Nitrosoethanolamine (NDE1A) was administered to male BD-VI rats, and its urinary excretion rate was measured to determine if a high rate could account for the low carcinogenicity of this compound. The rats received single doses of 1,000, 500, or 100 mg/kg NDE1A by gavage. Approx 70% of the dose was excreted unchanged in the urine within 24 hr. This percentage appeared to be independent of the absolute dose, at least within the range 10-1,000 mg/kg. However, since some of the urine may have been absorbed by the feces, the real excretion values may be somewhat higher. The amount collected within 24 hr represented 95% of the excreted dose; no urinary elimination of NDE1A occurred after 48 hr. These findings suggest that the low carcinogenicity of NDE1A is the result of a high and fast excretion rate, probably because of its low resorption through cellular membranes. (8 refs)

78-4302 **The Acute Effects of the Carcinogen DIPN on Pancreatic Secretion in Hamsters (Meeting Abstract).** (Eng) Roberts, C. (VA Hosp., San Francisco, CA); Reber, H. A. *Gastroenterology* 74(5, part 2): 1142; 1978. (no refs)

78-4303 **Chromosomal Aberrations in Rat Lymphocytes Treated In Vivo with 1-Phenyl-3,3-dimethyltriazene and N-Nitrosomorpholine. A Further Report on a Possible Method for Carcinogenicity Screening.** (Eng) Newton, M. F. (Dept. Biology as Applied to Medicine, Middlesex Hosp. Medical Sch., London W1P 6DB, England); Bahner, B.; Lilly, L. J. *Mutat Res* 56(1): 39-46; 1977.

The carcinogens N-nitrosomorpholine (NM) and 1-phenyl-3,3-dimethyltriazene (PDT) were screened for their ability to cause an increase in chromosomal aberrations in rat lymphocytes in vitro after treatment in vivo. NM was injected ip in doses of 200, 250, 300, and 400 mg/kg, and the rats were sacrificed 3 or 20 hr later. PDT was injected ip in doses of 3.5, 7.0, 35, and 50 mg/kg, and the animals were sacrificed 6 hr later. Lymphocyte preparations were cultured for 48 hr in the presence of phytohemagglutinin, and colchicine was added 1.5 hr before harvesting. NM caused a significant increase in the number of chromosomal aberrations after a single dose of 250 mg/kg or higher. These aberrations were mainly of the isolocus type. Significant increases in the number of isolocus- and chromatid-type aberrations were found after single doses of 35 and 50 mg/kg PDT, which are about half the amounts found to cause revertants of *Saccharomyces cerevisiae* in the host-mediated assay in mice. The positive results with PDT, which causes tumors mainly of the central and peripheral nervous systems, could imply the existence of an active circulating metabolite of PDT detectable by the chromosomal damage it causes to rat lymphocytes. The existence of such a long-lived metabolite may be necessary for the induction of tumors in the central and peripheral nervous systems. (18 refs)

78-4304 **Differential Metabolism of Geometrical Isomers of N-Nitroso-2,6-dimethylmorpholine in the Hamster.** (Eng) Gingell, R. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, 42nd and Dewey Ave., Omaha, NB, 68105); Nagel, D.; Kupper, R. *Xenobiotica* 8(7): 439-443; 1978.

The metabolism of the cis and trans isomers of the pancreatic carcinogen N-nitroso-2,6-dimethylmorpholine (NDMM) was studied in randomly bred male Syrian golden hamsters. The animals were inoculated ip with 100 mg/kg of either isomer as a 10-mg/ml soln in saline-propylene glycol (2:1). Both isomers were metabolized by B-oxidation and ring scission to N-nitroso-(2-hydroxypropyl)(2-oxopropyl)amine (HPOP), the suggested proximate pancreatic carcinogen, and to N-nitrosobis(2-hydroxypropyl)amine (BHP). Although the cis isomer produced slightly higher blood levels of NDMM and HPOP than the trans isomer, the differences are probably not biologically significant. The amounts of metabolites in the 24-hr urine were similar, and there was no unchanged NDMM, indicating little difference in the overall amount of metabolism of each isomer by β-oxidation. However, the initial rate of β-oxidation and urinary excretion of the cis isomer was much greater than that for the trans isomer, probably because a relative ease of enzymatic axial attack. Alternatively, the trans isomer may bind more weakly to the hepatic mixed-function oxidase, diminishing the rate of metabolism. However, since the accumulated 24-hr urine metabolites were similar, any anticipated difference in the carcinogenic potency of cis- and trans-NDMM in the hamster pancreas is likely to be minimal. (13 refs.)

78-4305 **Mutagenicity Screening on Pesticides and Modification Products: A Basis of Carcinogenicity Evaluation.** (Eng) Shirasu, Y. (Toxicology Div., Inst. Environmental Toxicology, Kodaira-shi, Tokyo 187, Japan); Moriya, M.; Kato, K.; Lienard, F.; Tezuka, H.; Teramoto, S.; Kada, T. *In: Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation.* Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 267-285; 1977.

The results of microbial mutagenicity screening studies, cytogenetic and dominant lethal studies of Captan [N-(trichloromethylthio)-4-cyclohexene-1,2-dicarboximide] and ethylenethiourea (ETU), and mutagenicity studies of the nitrosation products of pesticides are presented. The rec and reversion assays were used to screen 193 pesticides for mutagenicity in two strains of *Escherichia coli* and four strains of *Salmonella typhimurium* without metabolic activation. Fifteen pesticides were mutagenic: Captafol, Captan, Dexon, Dichlorvos, Folpet, N-(2-hydroxyethyl)hydrazine, 2,4-dinitrophenyl thiocyanate, 5-nitro-1-naphthonitrile, Vamidothion, Ferbam, Ziram, arsenic dimethyldithiocarbamate, bis(dimethylthiocarbamoyl)disulfide, N,N′-bis(dimethyldithiocarbamoyl)ethylenediamine, and Dichlofluanid. When liver homogenates from phenobarbital- or polychlorinated biphenyl-treated rats were used, the mutagenicity of some of the pesticides was either lost or enhanced. In cytogenetic studies of Captan, the incidence of chromosome aberrations in human diploid fibroblast cells treated in vitro (1.5, 3.0, or 4.0 μg/ml for 4 or 24 hr) was not increased significantly. Similar findings were obtained in vivo with male rats. Captan did not increase the rate of embryonic death at any spermatogenesis stage tested. Negative results were also obtained in in vivo cytogenetic and dominant lethal studies of ETU, which might be due to its organ affinity: metabolic studies revealed that ETU accumulated in the thyroid. Preliminary results of the nitrosation and mutagenicity testing of 120 pesticides that were negative in the rec and reversion assays are given. (42 refs.)

78-4306 **Testing of Known Carcinogens and Noncarcinogens for Their Ability to Induce Unscheduled DNA Synthesis in HeLa Cells.** (Eng) Martin, C. N. (Cancer Res. Unit, Univ. York, Heslington, York, Y01 5DD, England); McDermid, A. C.; Garner, R. C. *Cancer Res* 38(8): 2621-2627; 1978.

The ability of 51 chemical carcinogens and noncarcinogens to induce unscheduled DNA synthesis (UDS) in HeLa cells was tested in the presence or absence of a rat liver mixed function oxidase preparation. The chemicals tested included those giving erroneous results in bacteria mutagenicity assays and representative compounds from four classes of chemical carcinogens: nitrosamines polycyclic aromatic hydrocarbons, aromatic amines and mycotoxins. None of the noncarcinogens induced UDS. Of 38 documented carcinogens, 34 were active safrole, N-propyl-N-nitrosourea, aflatoxin B_2, and N butyl-1-N-nitrosourea were inactive. Six compounds for which carcinogenicity data are incomplete were active: 4-nitro-o-phenylenediamine, 2-nitro-p-phenylene diamine, formaldehyde, 2,2′-dichlorobenzidine, 3,3′, 5,5′-tetrafluorobenzidine, and 3,3′,5,5′-tetrachlorobenzi dine. Urethan, N-dimethyl-p-aminoazobenzene, and di ethylstilbestrol, carcinogens that are weakly active or inactive in bacterial mutagenicity assays, were active in the UDS assay. The bacterial mutagens sodium azide and 9-aminoacridine were inactive. The use of this assay in a tier scheme for the short-term testing of potential chemical carcinogens is discussed. (38 refs)

78-4307 **Mutagenicity and Cytotoxicity of Congeners of Two Classes of Nitroso Compounds in Chinese Hamster Ovary Cells.** (Eng) Couch, D. B. (Chemical Industry Inst. Toxicology, Research Triangle Park, NC, 27709); Hsie, A. W. *Mutat Res* 57(2): 209-216; 1978.

The induction of mutation by certain nitrosamidines and nitrosamides was quantitated using the hypoxanthine-guanine phosphoribosyltransferase locus in Chinese hamster ovary (CHO-K_1-BH_4) cells. Dose-response relationships for cytotoxicity and mutagenicity were observed for N-methyl-N-nitrosourea (MNU), N-ethyl-N-nitrosourea (ENU), N-butyl-N-nitrosourea (BNU), N-methyl-N′-nitro-N-nitrosoguanidine (MNNG), and N-ethyl-N′-nitro-N-nitrosoguanidine (ENNG). Although all the agents produced an exponential loss of clonal growth with increasing dose, nitrosoguanidines were more toxic than nitrosoureas, and within each class of compound, cytotoxicity declined with increasing size of the alkyl group. Based on the concentration of each agent required to kill 90% of the cells, the following order of cytotoxicity was observed: MNNG > ENNG > MNU > ENU > BNU. This is the same order of potency observed for mutation induction per unit concentration of mutagen. (14 refs.)

78-4308 **Fibrinolytic Activity of Cultured Cells Derived During Ethylnitrosourea-induced Carcinogene-**

sis of Rat Brain. (Eng) Hince, T. A. (Dept. Cell Pathology, Sch. Pathology, Middlesex Hosp. Medical Sch., Riding House St., London, W1P 7LD, England); Roscoe, J. P. *Br J Cancer* 37(3): 424-433; 1978.

Using a sequential in vivo/in vitro cell culturing approach, the fibrinolytic activity of cell lines derived from an ethylnitrosourea (ENU)-induced glioma, and cell lines derived during the latent period was determined. The intermediate cell lines were derived from fetuses or young rats 2-145 days after administration of 40 mg/kg ENU to the mothers after day 12 of gestation. High levels of plasminogen-dependent fibrinolytic activity were demonstrated in lines derived from the ENU-induced gliomas, but lines from normal adult rat brain showed only low levels of activity. The degree of lysis produced by a given cell line was dependent on the av number of cells per colony, and a different pattern of response was observed for tumor and normal cell lines. A positive correlation existed among the level of fibrinolytic activity, growth in agar, and tumorigenicity of a cell line. Fibrinolytic activity was associated with cell lines derived at various times in the latent period, before the appearance of a visible tumor. Many cell lines derived from rat brains at 57-60 (E7), 90-91 (E8), and 111-112 (E6) days after transplacental ENU exposure showed fibrinolytic activity, and in the latter group the close association with growth in agar and tumorigenicity was also demonstrated. With lines E7 and E8, the possession of fibrinolytic activity preceded the ability of cells to form colonies in agar. (26 refs)

78-4309 **Effect of Chloramphenicol on the Carcinogenicity of N-Nitrosomethylurea.** (Rus) Bogush, T. A. (Dept. Carcinogenic Agents, Cancer Res. Center, Moscow, USSR); Belitskii, G. A.; Shabad, L. M. *Biull Eksp Biol Med* 86(7): 61-63; 1978.

The effect of the antibiotic chloramphenicol (CA) on the carcinogenicity of N-nitrosomethylurea (NMU) was studied in CBA mice. Animals received CA (1 mg/g/day, intragastrically) for 5 days; 2 hr after the last CA administration, mice were inoculated sc with NMU (0.025-0.07 mg/g). NMU induced lymphomas, leukemias, hepatomas, renal cystadenomas, solid carcinomas, and adenocarcinomas of the uterus, ovaries, and prestomach. The av latent period of tumor development in mice exposed to 0.07 mg/g NMU was 158 days, compared with 208 days in mice treated with NMU + CA (incidence of tumor-bearing animals was 36.5% and 27.5%, respectively). The av latent period of tumor development in mice exposed to 0.025 mg/g NMU was 35.8 wk, compared with 54 wk in animals exposed to NMU + CA (incidence of tumor-bearing animals was 20% and 12% respectively). (8 refs.)

78-4310 **Human Exposure to N-Nitroso Compounds in the Environment.** (Eng) Fine, D. H. (Cancer Res. Dept., Thermo Electron Res. Center, Waltham, MA, 02154); Rounbehler, D. P.; Fan, T.; Ross, R. *In: Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation.* Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 293-307; 1977.

Two new aspects of human exposure to N-nitroso compounds are reported: in vivo nitrosation in humans due to ingestion of nitrite-preserved foodstuffs and the presence of excessive N-nitrosamine contamination in widely used herbicides. Chromatographic analysis of blood samples taken before and after ingestion of a midday meal consisting of 310 g spinach, 170 g cooked bacon, 200 g tomatoes, 120 g bread, and 460 g beer indicated that about 7 μg of nitrosamine [both N-nitrosodimethylamine (NDMA) and N-nitrosodiethylamine] were formed in vivo. However, the total amount of nitrosamine formation could have been greater, because the calculations did not take into account nitrosamine loss by metabolic processes or exhalation or the absorption of nitrosamine by fat and other tissues. Analysis of various herbicides formulated for home use revealed the presence of NDMA at levels as high as 0.06%. On the basis of these findings, it is suggested that epidemiologic studies be initiated to follow persons who may have been exposed to high levels of nitrosamine-containing formulations in the working environment (agricultural as well as manufacturing and formulating workers). Literature data on the presence of N-nitroso compounds in food, tobacco, air, water, and soil are reviewed. (31 refs.)

78-4311 **Oncogenicity of Purine 3-Oxide and Unsubstituted Purine in Rats.** (Eng) Teller, M. N. (Walker Lab., Sloan-Kettering Inst. Cancer Res., Rye, NY, 10580); Giner-Sorolla, A.; Stohrer, G.; Budinger, J. M.; Brown, G. B. *Cancer Res* 38(8): 2229-2232; 1978.

Sc injection of purine 3-oxide (7.5 or 0.75 mg 3x/wk for 8 wk) into Wistar rats resulted in the appearance of sarcomas and fibromas at the intercapsular site of administration, hepatocellular carcinomas, and a high incidence of sc fibromas in the hip area. A small number of liver tumors but no tumors at the injection site appeared in rats that received 6.5 or 0.65 mg of the parent compound, purine. Oxidation of purine 3-oxide by xanthine oxidase occurred in two steps to yield the potent oncogen 3-hydroxyxanthine. A similar process may occur in vivo, since a protein preparation from rat sc tissue has similar oxidizing activity. (19 refs)

78-4312 **Effect of Phorbol Myristate Acetate on Cyclic Nucleotide Levels in Mouse Epidermis.** (Eng) Belman, S. (Dept. Environmental Medicine, New York Univ. Medical Center, New York, NY, 10016); Troll, W.; Garte, S. J. *Cancer Res* 38(9): 2978-2982; 1978.

The effect of a single topical administration of phorbol myristate acetate (PMA) on cyclic AMP (cAMP) and cyclic guanosine 3′:5′-monophosphate (cGMP) levels in the epidermis 0-72 hr after treatment were determined in female Swiss Ha/ICR mice. An acetone soln of PMA (10 μg/0.2 ml) was applied to the depilated backs of the test animals. No changes in cAMP levels were found 0-72 hr after treatment, but a twofold increase in cGMP levels was apparent by 36 hr. However, this increase had subsided by 72 hr. PMA treatment stimulated DNA synthesis in a cyclic manner. There was a possible slight depression in thymidine incorporation into DNA at 3 hr followed by three peaks at 18, 42, and 60 hr. Incorporation of cytidine into RNA was slightly depressed at 1 hr, followed by two peaks at 3 and 18 hr. Values declined to control levels by 30 hr and remained unchanged. Protein synthesis was increased by 1 hr after PMA application, and it reached a max at 24 hr before declining to control values by 72 hr. (17 refs.)

78-4313 **Induction of Preneoplastic Hyperplasia and Carcinoma by N-Methyl-N′-nitro-N-nitrosoguanidine from Regenerated Mucosa of Ulcers Induced by Iodoacetamide in Fundus of Rat Stomach.** (Eng) Shirai, T. (First Dept. Pathology, Nagoya City Univ. Medical Sch., 1 Kawasumi, Mizuho-cho, Mizuho-ku, Nagoya 467, Japan); Takahashi, M.; Fukushima, S.; Tatematsu, M.; Hirose, M.; Ito, N. *Gann* 69(3): 361-366; 1978.

N-Methyl-N′-nitro-N-nitrosoguanidine (MNNG)-induced carcinogenesis in the regenerating mucosa of iodoacetamide (IAA)-induced stomach ulcers was studied in male Wistar rats. Both IAA (0.01%-0.1%) and MNNG (50 mg/liter) were administered in the drinking water. There were five groups of 25 animals. Group 1 was given IAA during weeks 1-12 and MNNG during weeks 16-28. Group 2 was given IAA and MNNG during weeks 16-28. Group 3 was given MNNG during weeks 16-28 and IAA during weeks 32-44 Group 4 was given MNNG during weeks 16-28, and Group 5 was given IAA during weeks 1-12. All animals were sacrificed at 60 wk. Pyloric gland metaplasia was found in the fundic ulcers of 15/17 Group 1 animals, 12/17 Group 2 animals, 10/15 Group 3 animals, and 15/18 Group 5 animals. Proliferative lesions, (atypical metaplasia) in the pyloric gland metaplasias were found in 10/17 Group 1 animals, 5/17 Group 2 animals, and 1/15 Group 3 animals. An adenocarcinoma was observed in the ulcerative region of two Group 1 animals. There was no significant difference in the incidence of hyperplasia, adenoma, and adenocarcinoma in the pyloric region between Groups 1, 2, and 3 animals and those in Group 4. An adenocarcinoma was also observed in the duodenum of a Group 2 rat. These findings indicate that gastric cancers can develop from ulcerative lesions and that pyloric gland metaplasia is more susceptible to MNNG than the rapidly regenerating mucosa at the margin of an ulcer. (10 refs.)

78-4314 **Quantification of Chemical Mutagenesis in Diploid Human Fibroblasts: Induction of Azaguanine-resistant Mutants by N-Methyl-N′-nitro-N-nitrosoguanidine.** (Eng) Jacobs, L. (Dept. Cytogenetics, Inst. Medical Res., Camden, NJ, 08103); Demars, R. *Mutat Res* 53(1): 29-53; 1978.

The toxic and mutagenic effects of N-methyl-N′-nitro-N-nitrosoguanidine (MNNG) were studied using cultured diploid human fibroblasts. When 10^5 cells were exposed to $<1 \times 10^{-6}$ M MNNG for 4 hr. cell survivals of almost 100% were observed; concentrations $>5 \times 10^{-6}$ M resulted in av cell survivals of <1%. Cells were then treated with 3.0 x 10^{-6} M MNNG and selected for resistance to azaguanine and thioguanine. The induced mutant frequency was maximized by allowing a 5-7-day posttreatment interval for the expression of the mutant phenotype and by replating the cells at the beginning of selection at a population density of <450 cells/cm^2. Independent dose-response experiments gave induced mutant frequencies as high as 7.0 x 10^{-4} to 8.8 x 10^{-4} mutants per viable cell at about 5% survival, compared with a spontaneous mutation rate of 3.7 x 10^{-6} to 7.2 x 10^{-6} mutants per generation. The azaguanine-resistant mutants observed after MNNG treatment were phenotypically stable, and they closely resembled prototype azaguanine-resistant cultures from humans with inherited mutant X-chromosomal alleles for hypoxanthine-guanine phosphoribosyltransferase. 78-4315 **Base and Base Sequence Specificity of the Binding of 4-Hydroxyaminoquinoline 1-Oxide to DNA.** (Eng) Gotoh, O. (Dept. Physics, Faculty Science, Univ. Tokyo, Hongo 7-3-1, Bunkyo-ku, Tokyo 113, Japan); Wada, A.; Tada, M.; Tada, M. *Gann* 69(1): 61-66; 1978.

The binding of 4-hydroxyaminoquinoline 1-oxide (4-HAQO), a metabolite of 4-nitroquinoline 1-oxide, to synthetic and natural DNA's was examined in vitro. With a standard enzyme concentration, the binding of 4-HAQO to poly(deoxyguanosine-deoxycytosine) [poly(dG-dC)]-poly(dG-dC), poly(dG)-poly(dC), poly(deoxyadenine-deoxythymidine) [poly(dA-dT)]-poly(dA-dT), λ-DNA, and poly(dA)-poly(dT) decreased in this order. These findings also indicate that a difference in base sequence leads to a different amount of binding: only a very small amount of 4-HAQO could bind to poly(dA)-poly(dT), but >10 times this amount could bind to poly(dA-dT)-poly(dA-dT). The optical melting profiles of the 4-HAQO-modified DNA's were examined. Decreases in the melting temperature and broadening of the transition width were commonly observed. The melting fine structure of the λ-phage DNA became less clear with modification. The shape of the melting curves of synthetic polynucleotides was not changed much by binding, suggesting that the binding sites are distributed randomly along a DNA molecule. The binding of 4-HAQO to a purine base may distort the secondary structure of the neighboring base pairs. The degree of distortion, estimated as a free energy increment associated with binding, differed considerably mong polynucleotides with different base sequences. (18 efs)

8-4316 **Microsomal N-Hydroxylation of trans-4′-Alkoxy-4-acetamidostilbenes.** (Eng) Gammans, R. . (USV Pharmaceutical Corp., Tuckahoe, NY); Sehon, R. .; Anders, M. W.; Hanna, P. E. *Drug Metab Dispos* 6(3): 26-231; 1978.

he influence of 4′-alkoxy substituents on the in vitro metab-ism of a series of trans-4-acetamidostilbenes (AAS's) by amster liver microsomes was studied. 4′-methoxy-AAS was onverted to a single ether-extractable metabolite, 4′-me-oxy-4-(N-hydroxy-AA)S, and 4′-ethoxy-AAS was convert-l to 4′-ethoxy-4-(N-hydroxy-AA)S, 4′-hydroxy-AAS, and -ethoxy-AAS α,β-epoxide. 4′-Butoxy-AAS was metabol-ed to the hydroxamic acid, 4′-butoxy-4-(N-hydroxy-AA)S, id it underwent (ω-1)-hydroxylation of the aliphatic chain, oducing 4′-(3-hydroxybutoxy)-AAS. 4′-Propoxy-AAS was onverted to 4′-propoxy-4-(N-hydroxy-AA)S and 4′ ropoxy-AAS α,β-epoxide. Attempts to examine the kinet-s of metabolism of 4′-methoxy-AAS and 4′-ethoxy-AAS oved unsuccessful. In contrast to these analogs, the metab-ism of 4′-butoxy-AAS followed Michaelis-Menten kinetics. -Alkoxy-AAS's were not metabolized when heat-inactivat-l microsomes were used or when the NADPH-generating stem was omitted. Although each substrate was converted a potentially toxic or carcinogenic arylhydroxamic acid, e rates of both bioactivation and the formation of presuma-y nonhazardous carbon oxidation products may be signifi-ntly influenced by suitable modification of the physico-emical properties of the substrates. (20 refs.)

3-4317 **Bilary Excretion of N,N-Dimethyl-4-aminoazobenzene (DAB) in the Rat. Effects of Pretreat-ent with Inducers and Inhibitors of the Mixed-Function xidase System and with Agents That Deplete Liver Glu-thione.** (Eng) Levine, W. G. (Dept. Molecular Pharmacolo-, Albert Einstein Coll. Medicine, Yeshiva Univ., Bronx, Y, 10461); Finkelstein, T. T. *Drug Metab Dispos* 6(3): 55-272; 1978.

ne biliary excretion of N,N-dimethyl-4-aminoazobenzene)AB) metabolites following a single iv injection of the C-labeled form of this dye was studied in male Wistar rats. ne biliary excretion of amaranth, an azo dye excreted almost tirely in nonmetabolized form, was also studied. After in-ction of ^{14}C-DAB in control animals, about 20%-25% of e radioactivity (RA) was excreted in 1 hr. In animals treat-l with 3-methylcholanthrene or phenobarbital to induce the ixed-function oxidase (MFO) system, the biliary excretion RA was markedly enhanced, especially in the early phase the collection period. In rats treated with the MFO inhibi-rs piperonyl butoxide or SKF 525-A, the biliary excretion RA was markedly suppressed throughout the collection period. Biliary excretion of RA was also suppressed after pretreatment with methyl iodide or diethyl maleate, which decrease liver glutathione (GSH) levels. Injection of a mixture of ^{14}C-DAB metabolites from animals treated with ^{14}C-DAB stimulated the excretion of biliary RA to a greater extent than did injection of ^{14}C-DAB. GSH-depleting agents and MFO inducers and inhibitors had no effect on the rate of excretion of injected metabolites. Pretreatment with nafenopin did not affect the excretion of ^{14}C-DAB metabolites, and the binding of DAB or its metabolites to Z protein was limited by the concentration of Z in the liver. The excretion of RA was as rapid after the injection of unconjugated metabolites as after the injection of conjugated metabolites. Free 4-aminoazobenzene was excreted relatively slowly. The results indicate that metabolism is the rate-determining step in the biliary excretion of DAB and that liver GSH is involved in the biliary fate of DAB. (45 refs.)

78-4318 **Studies in Rats of the Mechanism of Organotropy and Metabolism of the Colon Carcinogen Methylazoxymethanol Acetate (Meeting Abstract).** (Eng) Zedeck, M. S. (Sloan-Kettering Inst., New York, NY); Grab, D. J.; Frank, N.; Wiessler, M.; Bertram, B.; Schmahl, D. *Digestion* 16(3): 288; 1977. (1 ref)

78-4319 **Mutagenicity Testing of Certified Food Colors and Related Azo, Xanthene and Triphenylmethane Dyes with the Salmonella/Microsome System (Meeting Abstract).** (Eng) Brown, J. P. (Dynapol, Palo Alto, CA, 94304); Roehm, G. W.; Brown, R. J. *Mutat Res* 53(1): 70; 1978. (no refs)

78-4320 **Direct Black 38, Direct Blue 6, Direct Brown 95, Benzidine Derived Dyes.** (Eng) Thomas, A. W. (Natl. Inst. Occupational Safety and Health, 5600 Fishers Lane, Rockville, MD, 20852); Boeniger, M. F.; Weber, M. G.; Stein, H. P.; Upton, A. C.; Millar, J. D. *Am Ind Hyg Assoc J* 39(8): A18-A24; 1978.

Studies that led to the recommendation by the National Institute for Occupational Safety and Health that the three benzidine (BZD)-derived dyes Direct Black 38, Direct Blue 6, and Direct Brown 95 be handled as if they were human carcinogens are summarized. All three dyes produced significant incidences of cancerous and precancerous changes in the livers of male and female rats given these compounds in the feed for 90 days. The damage was similar to that caused by BZD. In the same feeding test with mice, all three dyes were harmful to the liver but no cancerous changes were found. This finding is compatible with the interpretation that the toxic effects may be related to BZD, as this compound is more likely to produce cancer in rats than mice. Although the dyes were BZD-free when fed to the animals, substantial amounts of BZD were found in the urine of both rats and mice. The urine of workers at two BZD dye manufacturing plants and two textile finishing companies contained BZD or its metabolite monacetybenzidine (MAB). In one of the dye manufacturing plants, workers exposed only to the finished dyes had about 20 times more BZD and up to 200 times more MAB in their urine than if they had been exposed only to the residual BZD content in the dyes. It is suggested that preventing the worker inhalation of the dye particles would greatly reduce BZD absorption by the body. (18 refs.)

78-4321 **Kidney and Liver Tumors in Rats from 4,4′-Methylene Bis(2-carbomethoxyaniline).** (Eng) Stula, E. F. (Haskell Lab., Elkton Road, Newark, DE, 19711); Sherman, H.; Barnes, J. R.; Aftosmis, J. G. *J Environ Pathol Toxicol* 1(3): 199-209; 1978.

The carcinogenicity of 4,4′-methylene bis(2-carbomethoxyaniline), also known as methylene-bis methyl anthranilate (MBMA), was investigated in ChR-CD weanling rats (Charles River cesarean-derived, Sprague-Dawley origin, barrier-sustained, random-bred albino). Groups of 50 rats of each sex were fed diets containing 0, 1,500, or 15,000 ppm MBMA for up to 2 yr. At both dietary levels, MBMA caused slight degenerative histologic changes in the liver and kidney of both sexes. Male rats receiving 15,000 ppm MBMA showed a statistically significant increase ($p < 0.05$) in kidney and liver tumors compared with controls, and females on the same dose had an elevated kidney tumor incidence compared with controls ($p < 0.10$). There was a statistically significant lower incidence of pituitary tumors in males ($p < 0.05$) and in females ($p < 0.10$) receiving 15,000 ppm MBMA compared with controls; the females also showed a lower incidence of mammary tumors ($p < 0.05$) compared with controls. The lower incidence of pituitary and mammary tumors in MBMA-fed rats than in controls suggests a possible endocrine effect produced by MBMA. Since MBMA-related tumors were not found until 18 mo after the initiation of a relatively large MBMA dose (1.5% of the diet), the compound is considered to be a carcinogen of moderate potency. (7 refs)

78-4322 **Methemoglobin Formation and Binding to Blood Constituents as Indicators for the Formation, Availability and Reactivity of Activated Metabolites Derived from trans-4-Aminostilbene and Related Aromatic Amines.** (Eng) Wieland, E. (Institut fur Pharmakologie und Toxikologie, Universitat Wurzburg, Versbacher Landstrasse 9, D-8700 Wurzburg, W. Germany); Neumann, H. G. *Arch Toxicol (Berl)* 40(1): 17-35; 1978.

Female Wistar rats were used to study the interactions of aminostilbene derivatives with blood constituents. The compounds were administered by stomach tube or iv injection, and methemoglobin (MHb) formation was measured for up to 4 hr. Interactions with blood constituents were also studie in vitro. After po administration, neither trans-4-dimethylaminostilbene nor the less toxic 4-dimethylaminodiben zyl raised the MHb level appreciably. After iv injection of th amino or the nitroso derivatives, however, considerable MH induction was observed. The less toxic dibenzyl compound produced more MHb than the trans-stilbene analogs. The results were confirmed by in vitro experiments with suspensions of rat RBC. The respective amines were inactive, an p-tolylhydroxylamine was as active as the nitroso compoun in this system. After the addition of labeled compounds t whole blood, 60%-70% of trans-4-nitrosostilbene and 4-nitrosodibenzyl was found in the RBC, and most of the radioactivity was bound to Hb. trans-4-Aminostilbene also exhibite affinity for the RBC (65%), but the radioactivity was no bound to Hb; aminodibenzyl did not enter the RBC to a appreciable extent. In vivo, trans-4-aminostilbene an 4-aminodibenzyl were N-oxidized to a similar extent, and th primary activation products of the former appeared even faster in the blood. However, intermediates originating durin MHb formation were more reactive and the trans-stilben derivatives bound two to three times more to Hb than th dibenzyl derivatives. The results indicate that binding to H and not the level of MHb is an indicator of the availabilit and reactivity of some activated aromatic amine metabolites (47 refs)

78-4323 **Identification and Quantitation of 3-Hydroxy-N-nitrosopyrrolidine in Fried Bacon** (Eng) Lee, J. S. (Dept. Food Science and Technology, Orego State Univ., Corvallis, OR, 97331); Libbey, L. M.; Scanla R. A.; Bills, D. D. *Bull Environ Contam Toxicol* 19(5 511-517; 1978.

3-Hydroxy-N-nitrosopyrrolidine (HNPYR) was identifie and quantitated in commercial fried bacon by gas chromatography and mass spectrum analysis of its trimethylsilyl derivative. HNPYR levels, relative to bacon wt, ranged from 0. to 3.9 ppb. (10 refs.)

78-4324 **Stereochemical Assignment of (E)- an (Z)-2-(1-Naphthyl)-1-phenylpropene and Thei Photocyclization to 5-Methylchrysene.** (Eng) Browne, C. E (Dept. Chemistry, Oklahoma State Univ., Stillwater, OK 74074); Dobbs, T. K.; Hecht, S. S.; Eisenbraun, E. J. *J Org Chem* 43(9): 1656-1660; 1978.

A shorter and improved synthesis (20% yield) of the carcinogen 5-methylchrysene (5MC) via UV irradiation of (E)- o (Z)-2-(1-naphthyl)-1-phenylpropene (ENP or ZNP), wa developed. Dehydration of 2-(1-naphthyl)-1-phenyl-2-propanol gave varying ratios of ENP, ZNP, and 2-(1-naphthyl)-3-phenylpropene, depending on the choice of reagent and photocyclization of ENP and ZNP gave 5MC. (23 refs)

8-4325 **Mutagenicity of Anthraquinones in the Salmonella/Microsome System: Activation of Anhraquinone Glucosides by Gut Bacterial Enzymes (Meeting bstract).** (Eng) Brown, J. P. (Dynapol, Palo Alto, CA, 4304); Roehm, G. W.; Brown, R. J. *Mutat Res* 53(1): 69-70; 978. (no refs)

8-4326 **Relationships Between Carcinogenicity and Theoretical Reactivity Indices in Polycyclic romatic Hydrocarbons.** (Eng) Smith, I. A. (Dept. Chemisy, Univ. California at San Diego, La Jolla, CA, 92093); erger, G. D.; Seybold, P. G.; Serve, M. P. *Cancer Res* 38(9): 968-2977; 1978.

heoretical reactivity indices were used to examine the metaolic reactions presumed responsible for the transformation f polycyclic aromatic hydrocarbons (PAH'S) to ultimate arcinogens. Twenty-five representative PAH's and their preumptive metabolites were analyzed. Of a large number of ndices examined, several showed a strong correlation with he carcinogenic activity of the test compounds. These findngs support the belief that specific transformations involving ihydrodiol, "bay-region" epoxide, and carbonium ion interediates are responsible for the carcinogenic activity of these ompounds. This type of analysis may provide a rapid and imple means for prescreening compounds for potential carinogenicity. (40 refs.)

78-4327 **Changes of the Cell Cycle During Carcinogenesis of Hamster Cheek Pouch Epithelium by ,12-Dimethylbenz(a)anthracene.** (Eng) Nagamine, Y. Dept. Pathology, Yamaguchi Univ. Sch. Medicine, 1144 Kogushi, Ube 755, Japan). *Gann* 69(3): 317-322; 1978.

he kinetic characteristics of 7,12-dimethylbenz(a)anthraene (DMBA)-induced hyperplastic and papillomatous epihelium in the cheek pouches of female Syrian hamsters were etermined. One cheek pouch was painted with 0.1 ml of a .5% soln of DMBA three times a week for 5 wk; in some nimals, the treatment was continued for >8 wk. Small tuors developed in several hamsters by day 47 and in all animals by day 67. DMBA treatment resulted in a progressive cceleration in the cell cycle, with the mean cycle times in he hyperplastic and neoplastic stages being approx wo-thirds and one-third of the control value, respectively. he G_1 phase was the one that was reduced the most. Most umor doubling times ranged from 100 to 150 hr, but the edian was between 200 and 250 hr. A nominal growth fracion exceeded unity in both the hyperplastic and neoplastic pithelium, indicating that a considerable number of cells in hich DMBA stimulated DNA synthesis failed to enter itosis. The inability of repair synthesis to restore DMBA-induced damage completely could also account for he failure of stimulated cells to enter mitosis. (25 refs.)

78-4328 **Biotransformation and Bioactivation of 7,12-Dimethylbenz(a)anthracene in Human Fetal and Placental Tissues. Analyses of HPLC Profiles and Studies with *Salmonella typhimurium*.** (Eng) Juchau, M. R. (Dept. Pharmacology, Sch. Medicine SJ-30, Univ. Washington, Seattle, WA, 98195); Namkung, M. J.; Jones, A. H.; DiGiovanni, J. *Drug Metab Dispos* 6(3): 273-281; 1978.

The capacity of human fetal and placental enzymes to catalyze the mixed-function oxygenation of 7,12-dimethylbenz(a)anthracene (DMBA) was studied. The metabolites formed in vitro were separated by high-pressure liquid chromatography (HPLC) and tentatively identified based on comparative HPLC retention times of known standard compounds. Comparisons were made with the commonly utilized substrate benzo(a)pyrene (BP), and the capacity of human fetal and placental tissues to generate mutagenic metabolites from DMBA was assessed with *Salmonella typhimurium* auxotrophs. The profiles of metabolites formed in incubation flasks containing fetal livers, lungs, kidneys, or adrenals were in general qualitatively similar to those observed using preparations of adult rat or rhesus monkey livers. The kidney exhibited the highest activities in each of the fetuses investigated. Profiles of metabolites from the placentas of women who smoked were markedly different from those of other tissues investigated, with large concentrations of metabolites appearing in the diol region. With BP as substrate, the metabolites cochromatographed largely with phenols and quinones. Placental microsomes from nonsmokers produced DMBA and BP profiles with minimal or no metabolites. The total metabolites formed from DMBA and BP were generally similar. Human fetal and placental tissue enzymes also catalyzed the formation of hydrocarbon metabolites mutagenic to various tester strains of *S. typhimurium*. (42 refs.)

78-4329 **Statistical Evaluation of Pienta's In Vitro Carcinogenesis Assay.** (Eng) Umezawa, K. (Dept. Molecular Oncology, Inst. Medical Science, Univ. Tokyo, 4-6-1, Shirogaendai, Minato-ku, Tokyo 108, Japan); Hirakawa, T.; Tanaka, M.; Katoh, Y.; Takayama, S. *Toxicol Lett* 2(1): 23-27; 1978.

The in vitro carcinogenesis assay developed by Pienta was evaluated statistically on the basis of eight experiments in which hamster embryo cells were exposed to 3-methylcholanthrene (3-MC: 0.1, 0.5, or 1.0 μg/ml) dissolved in dimethyl sulfoxide (DMSO: 0.2%) or to DMSO alone. No transformation was detected in DMSO controls or tissue culture controls, but 3-MC induced an av of 7.38 transformed colonies. The biomodal distribution of 3-MC transformation was calculated to determine the risk of a false negative. The results indicate that a positive result in the assay is reliable, but that there is a high risk of a false-negative result with chemicals possessing low transformation efficiency. This risk can be reduced by repeating the experiments. (5 refs)

78-4330 **Enhancement of Carcinogenesis by Prostaglandins.** (Eng) Lupulescu, A. (Medical Res. Building, Wayne State Univ., Detroit, MI, 48201). *Nature* 272(5654): 634-636; 1978.

The effects of prostaglandin E$_2$ (PGE$_2$) and prostaglandin F-2α (PGF-2α) on skin tumors induced by 3-methylcholanthrene (MCA) were examined in male albino Swiss mice. Mice were treated (1) topically with 0.2 ml of a 0.4% soln of MCA 3x/wk for 2 mo, (2) with MCA and, concomitantly, 10 μg PGE$_2$ im 3x/wk for 2 mo, or (3) with MCA and, concomitantly, 10 μg PGF-α im 3x/wk for 2 mo. Two additional groups were treated with each PG alone. At the end of 2 mo and 2 hr before they were sacrificed, mice from each group received an im injection of ^{3}H-thymidine, ^{3}H-uridine, ^{3}H-leucine, or ^{3}H-proline. Multiple and large tumors occurred after 2 mo in 90% of both the MCA plus PGE$_2$- and MCA plus PGF$_2$-treated mice at the treatment site. No tumors were observed in mice treated with MCA, PGE$_2$, or PGF-2α alone. There was a marked increase (15 to 20-fold) of ^{3}H-thymidine, followed by ^{3}H-uridine, ^{3}H-proline, and ^{3}H-leucine, in homogenized material from tumors of MCA plus PGE$_2$- and MCA plus PGF-2α-treated mice compared with those from MCA- or PG-treated or control epidermis. In investigations using MCA alone, tumors occurred only after 4 mo and usually after 5-6 mo; the PG's therefore, decreased the latent period by at least 65%. The PGE$_2$ and PGF-2α stimulation of DNA, RNA, and protein synthesis in hyperplastic epidermal cells following MCA application could explain the enhancement of cutaneous carcinogenesis and shortening of the latent period. (10 refs.)

78-4331 **Activities of 3,4-Benzpyrene Hydroxylase Systems Reconstituted by Means of Self-Assembly from Control and 3-Methylcholanthrene-induced Liver Microsomes of "Susceptible" and "Unsusceptible" Mice.** (Eng) Lyakhovich, V. V. (Dept. Biochemistry, Acad. Medical Sciences USSR, Novosibirsk 630091, USSR); Tsyrlov, I. B.; Gromova, O. A.; Rivkind, N. B. *Biochem Biophys Res Commun* 81(4): 1329-1335; 1978.

The self-assembly of 3,4-benzpyrene (3,4-BP) hydroxylase from solubilized proteins and lipids of control and 3-methyl-cholanthrene (MCA)-induced liver microsomes from mouse strains differing in susceptibility to 3,4-BP hydroxylase induction by polycyclic hydrocarbons was compared. The self-assembly was much more efficient in MCA-induced microsomes from induction-susceptible C57B1/6 mice and (C57B1/6 x DBA/2)F$_1$ hybrids than in control microsomes of these mice. In contrast, the self-assembly efficiency of MCA-treated microsomes from DBA/2 mice was no higher than that of the control microsomes of this strain. These data suggest that the regulation of the aggregation process during the molecular morphogenesis of endoplasmic membranes in mice is inherited as a dominant characteristic. (16 refs)

78-4332 **Rejection of Dinitrochlorobenzene-conjugated Syngeneic Tumor Cells by Dinitrochlorobenzene-Sensitized Guinea Pigs.** (Eng) Roth, J. A. (Dept. Surgical Services, Veterans Hosp., Sepulveda, CA, 91343); Morton, D. L.; Holmes, E. C. *J Surg Res* 25(1): 1-7; 1978.

The effect of dinitrochlorobenzene (DNCB), which can be easily conjugated to cells as dinitrophenyl (DNP), on the growth of a methylcholanthrene-induced sarcoma (MCA-25) in inbred female strain-2 guinea pigs was studied. MCA-25 tumor was conjugated to DNCB without significant loss of viability. Half of the animals were presensitized with 0.1 ml of a 20-mg/ml soln of DNCB injected id. All animals received 10^7 conjugated or unconjugated tumor cells injected id into both flanks. There was no significnat difference in tumor growth between sensitized and unsensitized animals. DNCB-conjugated tumor cells grew well in 17/22 animals not sensitized to DNCB, compared with only 8/21 sensitized animals. In addition, the DNCB-conjugated tumor cells grew significantly more slowly in the latter. Unconjugated tumor cells grew well in 18/20 unsensitized animals, even though they received a simultaneous injection of DNCB-conjugated cells. However, the growth of unconjugated tumor cells was inhibited by the simultaneous injection of conjugated tumor cells in sensitized animals. The results indicate that animals sensitized to hapten will not only reject hapten-conjugated tumor cells, but will also reject simultaneously injected unconjugated tumor cells. (15 refs.)

78-4333 **Competitive Binding and Metabolism of Several Carcinogenic Polycyclic Aromatic Hydrocarbons by AKR Mouse Embryo Cells in Culture.** (Eng) Zytkovich, T. H. (Dept. Molecular Medicine, Mayo Clinic, Rochester, MN, 55901); Moses, H. L.; Spelsberg, T. C. *Cancer Res* 38(8): 2307-2313; 1978.

The binding of ^{3}H-benzo(a)pyrene (BP), ^{3}H-benzo(a)anthracene [DB(a,h)A], and ^{3}H-dibenz(a,c)anthracene [DB(a,c)A] to nuclear chromatin was examined in cultured AKR mouse embryo cells. The covalent binding of the tritiated carcinogens to the nuclear substrates was inhibited effectively by 7,8-benzoflavone and by four unlabeled potent carcinogens: BP, DB(a,h)A, DB(a,c)A, and 3-methylcholanthrene. The weak carcinogens pyrene and anthracene had much less of an effect on this binding. Because covalent binding is a metabolically dependent event, the effects of the unlabeled compounds on the metabolism of the three tritiated compounds were also evaluated. The potent carcinogens inhibited the metabolism of the labeled compounds, causing decreased nuclear binding of the latter. Anthracene and pyrene stimulated the metabolism and had a variable effect on nuclear binding. The ability of the unlabeled compounds to compete with the metabolism and nuclear binding of the labeled carcinogens was apparently related to their carcinogenic potency. The data suggest the existence of a common metabolic pathway for potent carcinogens that differs, at least in part, from that of weak carcinogens. (43 refs)

78-4334 **Fine Structural Alterations Induced in Erythrocytes by Phorbol Myristate Acetate.** (Eng)

Vhite, J. G. (Dept. Pediatrics, Univ. Minnesota Medical ich., Box 479 Mayo Memorial Building, Minneapolis, MN, 5455); Repine, J. E. *Am J Pathol* 91(3): 571-580; 1978.

Previous studies have demonstrated that 12-O-tetradecanoyl-phorbol-13-acetate (phorbol myristate acetate, PMA) is a po-ent membrane-active agent causing cell wall-derived vacuole ormation in neutrophils and granule labilization in platelets. The present investigation demonstrates that PMA (2 x 10^{-6}, x 10^{-5}, or 1 x 10^{-4} M) also has marked effects on normal uman RBC. RBC exposed to PMA were converted into tomatocytes and stomatospherocytes. The effects of PMA vere concentration-dependent, required removal of plasma, nd were max at 37 C. Although the response of RBC to PMA was not identical to that of other blood cells tested previously, the similarities suggest that the capacity of the gent to produce membrane invagination may be fundamen-al to its mode of action. (23 refs.)

8-4335 **Plasma Membrane Alterations in Cultured Myogenic Cells Treated with the Tumor Pro-noter Tetradecanoylphorbol-13-Acetate (Meeting Abstract).** Eng) Schimmel, S. D. (Dept. Biochemistry, Univ. South Florida Coll Medicine, Tampa, FL, 33612); Keldie, V. C. *Fed Proc* 37(6): 1817; 1978. (no refs)

8-4336 **A Cell Culture Bioassay to Analyze Metabolism of Phorbol Diester Tumor Promoters.** (Eng) O'-Brien, T. G. (Wistar Inst. Anatomy and Biology, Phila-delphia, PA, 19104); Diamond, L. *Cancer Res* 38(8): 2567-2572; 1978.

The tumor promoter 12-O-tetradecanoylphorbol-13-acetate TPA) induces ornithine decarboxylase (ODC) in confluent monolayers of transformed hamster cells and potentiates the nduction of ODC in these cells by fresh medium. This obser-vation is the basis of a method that assays the metabolism of phorbol diester tumor promoters by the loss of their ODC-inducing activity. TPA-containing medium exposed to growing hamster embryo fibroblasts (HEF) for various lengths of time showed a rapid and progressive loss of the ability to potentiate ODC induction in transformed hamster cells, suggesting that the TPA had been metabolized. No loss of ODC-inducing activity occurred when TPA was exposed to cultures of growing or confluent human fibroblasts for 7 days. Mixing experiments with TPA-containing 'conditioned' medium from cultures of HEF and human fibroblasts indicated that HEF treated with TPA did not elaborate an inhibitor of ODC induction. This bioassay procedure was compared with the direct analysis of ^{3}H-TPA metabolism by thin-layer chromatography; the striking differences between hamster and human fibroblasts in their ability to metabolize TPA were confirmed. Cells from several other rodent species also metabolized TPA, but none of the four human cell lines tested, including SV40-transformed lines, metabolized the compound. The bioassay procedure was also used to measure metabolism of other phorbol diesters. Phorbol-12,13-didecanoate exposed to HEF did not lose its ability to induce ODC but phorbol-12,13-dibenzoate did. These results indicate that its metabolism renders TPA biologically inactive, as measured by ODC-inducing activity. However, not all phorbol diesters are metabolized by a given cell type, nor does their metabolism always lead to loss of biological activity. It is concluded that the chromatographic procedure plus the bioassay can be used to analyze the relationship between the chemical structure and biological activity of phorbol diester tumor promoters. (23 refs)

78-4337 **Effects of Phorbol-12-myristate-13-acetate on the Phenotypic Program of Cultured Chondroblasts and Fibroblasts.** (Eng) Lowe, M. E. (Dept. Anatomy, Univ. Pennsylvania Medical Sch., Philadelphia, PA, 19104); Pacifici, M.; Holtzer, H. *Cancer Res* 38(8): 2350-2356; 1978.

Phorbol-12-myristate-13-acetate (PMA: 5 x 10^{-8} M) had a prompt, differential, and partially reversible effect on cultured chick chondroblasts. Within 36 hr, PMA transformed sessile, polygonal, epithelioid chondroblasts into motile, multilayered, fibroblastic cells. By 48 hr, the chondroblasts no longer synthesized their type IV sulfated proteoglycan or a 180,000-dalton glycosylated protein that constitutes approx 5% of the total protein in normal chondroblasts. The effect of PMA on chondroblast morphology and protein synthesis was reversible after 4 days in PMA-containing medium but not after 12 days. PMA altered the morphology of chick fibroblasts, but it did not block the synthesis of their characteristic type III sulfated proteoglycan. PMA was mitogenic for the chondroblasts but not for the fibroblasts, in spite of the phenotypic similarities of these two cell types. (37 refs)

78-4338 **The Microsomal Metabolism of Benzo(a)pyrene Phenols.** (Eng) Capdevila, J. (Dept. Biochemistry, Univ. Texas Health Science Center at Dallas, 5323 Harry Hines Blvd., Dallas, TX, 75235); Estabrook, R. W.; Prough, R. A. *Biochem Biophys Res Commun* 82(2): 518-525; 1978.

Difference spectrophotometry coupled with high-performance liquid chromatography (HPLC) was used to monitor the steady-state metabolism of 3- and 9-hydroxybenzo(a)pyrene (9-OHBP) by liver microsomes from 3-methylcholanthrene-pretreated rats. The microsomal metabolism of 9-OHBP was accompanied by a progressive loss of absorbance at approx 421 nanometers (nm), concomitant with increases in absorbance at 409 and 436 nm. The two major 9-phenol metabolites had absorbance bands at 427 and 435 nm. Appreciable absorbance was also generated above 450 nm, suggesting that a small amount of BP quinones may exist during the steady state of the reaction. Experiments using 3-OHBP yielded difference spectra similar to those obtained with the 9-phenol. HPLC analysis revealed two major polar metabolites of 9-OHBP whose retention times relative to the 3-phenol were 0.59 and 0.68 min. These compounds had chromatographic properties similar to those of the 7,8-dihydrodiol of BP, and the optical and fluorescence emission spectra were similar to those of 9-OHBP. The effect of base titration on the fluorescence emission spectra was similar to the effect seen with the 9-phenol. HPLC also revealed two metabolites of ^{14}C-3-OHBP: the major metabolite had a retention time (0.83 min) and absorbance spectrum identical to those of BP 3,6-quinone; the second metabolite had a retention time of 0.59 min, similar to that of 3-OHBP, and an absorbance spectrum identical to that of the first metabolite of 9-OHBP. The results indicate that the liver microsomal fraction contains an oxygenase capable of metabolizing BP phenols to diphenols. (15 refs.)

78-4339 **Regio- and Stereoselectivity of Various Forms of Purified Cytochrome P-450 in the Metabolism of Benzo(a)pyrene and (-)trans-7,8-Dihydroxy-7,8-dihydrobenzo(a)pyrene as Shown by Product Formation and Binding to DNA.** (Eng) Deutsch, J. (Chemistry Branch, NCI, NIH, Bethesda, MD, 20014); Leutz, J. C.; Yang, S. K.; Gelboin, H. V.; Chiang, Y. L.; Vatsis, K. P.; Coon, M. J. *Proc Natl Acad Sci USA* 75(7): 3123-3127; 1978.

Highly purified cytochromes P-450-LM2 and P-450-LM4 and partially purified P-450-LM1, P-450-LM3b, and P-450-LM7 from rabbit liver microsomes exhibited different catalytic activities in the metabolism of benzo(a)pyrene (BP) and (-)trans-7,8-dihydroxy-7,8-dihydrobenzo(a)pyrene [(-)trans-7,8-diol] in a reconstituted enzyme system. The two highly purified cytochromes also exhibited differences in the activation of BP and (-)trans-7,8-diol to intermediates that bind to DNA, as well as in the stereoselective conversion of (-)trans-7,8-diol to the highly mutagenic and carcinogenic diol-epoxides r-7,t-8-dihydroxy-t-9,10-oxy-7,8,9,10-tetrahydro-BP (diol-epoxide I) r-7,t-8-dihydroxy-t-9,10-oxy-7,8,9,10-tetrahydro-BP (diol-epoxide II). P-450-LM2 was more active than P-450-LM4 in the metabolism of BP and in its conversion to products that bind to DNA. In contrast, P-450-LM4 is more active than P-450-LM2 in the metabolism of (-)trans-7,8-diol and in its conversion to products that bind to DNA. The radio of activity (percent substrate metabolized) with BP relative to that with (-)trans-7,8-diol is 21 for P-450-LM2 and 0.3 for P-450-LM4; P-450-LM1, P-450-LM3b, and P-450-LM7 gave intermediate ratios. Marked stereoselectivity in the oxygenation of the *trans*-7,8-diol to the highly mutagenic and putatively carcinogenic diol-epoxides I and II was observed with P-450-LM4, whereas the other preparations showed less selectively. The ratio of diol-epoxide I to diol-epoxide II ranged from 0.3 for P-450-LM7 to 11 for P-450-LM4. The substrate specificity and regio- and stereoselectivity of the different forms of cytochrome P-450 may regulate the balance between the activation and detoxification pathways of BP and, therefore, determine the susceptibility of individual tissues, strains, anc species to the carcinogenic action of BP. (43 refs.)

78-4340 **Tumorigenicity Studies with Diol-Epoxides o Benzo(a)pyrene Which Indicate that (±)-trans 7β,8α-Dihydroxy- 9α,10α-epoxy- 7,8,9,10 tetrahydrobenzo(a)pyrene is an Ultimate Carcinogen in Newborn Mice.** (Eng) Kapitulnik, J. (Dept. Pharmacology Hadassah-Hebrew Univ. Medical Sch., Jerusalem, Israel) Wislocki, P. G.; Levin, W.; Yagi, H.; Jerina, D. M.; Conney A. H. *Cancer Res* 38(2): 354-358; 1978.

The tumorigenicity of low equimolar doses of benzo(a)pyren (BP), (±)- trans -7β,8αdihydroxy-9β,10β-epoxy-7,8,9,1 tetrahydrobenzo(a)pyrene (diol-epoxide 1), (±)-tran 7β,8α- dihydroxy -9α,10α- epoxy-7,8,9,10-tetrahydr benzo(a)pyrene (diol-epoxide 2), (±)-trans- 7,8 dihydroxy- 7,8-dihydrobenzo(a)pyrene (BP 7,8-dihydrodiol) and the tetraols derived from the spontaneous hydrolysis o diol-epoxide 2 were evaluated in newborn Swiss-Webste mice. The mice were injected ip with 4, 8 and 16 nmoles o one of the test compounds on the 1st, 8th, and 15th days o life, and were sacrificed at 28 wk. Diol-epoxide 1 was highl toxic in newborn mice, and most of the animals given thi compound died before weaning. Diol-epoxide 2 and BP 7,8-dihydrodiol were about 40- and 15-fold more active, respectively, than BP in causing pulmonary adenomas. Diol-epoxide 1 and the tetraols derived from diol-epoxide 2 di not induce pulmonary adenomas. These results indicate tha diol-epoxide 2 is an ultimate carcinogenic metabolite and tha BP 7,8-dihydrodiol is a proximate carcinogenic metabolite o BP in newborn mice. The results also provide support for th proposal that diol epoxides, in which the epoxide ring form part of a bay region of the hydrocarbon, are of key importance for the carcinogenicity of BP and benz(a)anthracene (47 refs.)

78-4341 **Relationship Between Somatic Mutation an Neoplastic Transformation.** (Eng) Barrett, J. C (Div. Biophysics, Sch. Hygiene and Public Health, Johns Hopkins Univ., Baltimore, MD, 21205); Ts'o, P. O. *Proc Nat Acad Sci USA* 75(7): 3297-3301; 1978.

The somatic mutation (SM) and neoplastic transformatio (NT) of diploid Syrian hamster embryo cells were examine concomitantly. Mutations induced by benzo(a)pyrene an N-methyl-N'-nitro-N-nitrosoguanidine were quantitated a the hypoxanthine phosphoribosyltransferase and Na+/K+ ATPase loci and compared to phenotypic transformation measured by changes in cellular morphology and colony formation in agar. Both cellular transformations had characteristics distinct from the SM's observed at the two loci. Morphological transformation was observed after a tim comparable to that of SM but at a frequency that was 25- to 540-fold higher. Transformants capable of colony formation n agar were detected at a frequency of 10^{-5}-10^{-6}, but not until 32-75 population doublings after carcinogen treatment. Although this frequency of transformation is comparable to that of SM, the detection time required is much longer than the optimal expression time of conventionally studied SM's. NT of hamster embryo cells has been described as a multistep, progressive process. Various phenotypic transformations of cells after carcinogen treatment may represent different stages in this progressive transformation. The results are discussed in this context, and the role of mutagenesis in the transition between various stages is considered. NT may be nitiated by a mutational change, but it cannot be described completely by a single gene mutational event involving a dominant, codominant, or X-linked recessive locus. NT induced by chemical carcinogens is more complex than a single gene mutational process. Thus, this comparative study does not give experimental support to predictions of the carcinogenic potential of chemicals based on a simple extrapolation of the results obtained from conventional SM assays. (28 refs.)

78-4342 **Metabolism of Benzo(a)pyrene and Its Major Metabolites to Ethyl Acetate-soluble and Water-soluble Metabolites by Cultured Rodent Trachea.** (Eng) Moore, B. P. (Natl. Inst. Res. Dairying, Shinfield, Reading RG2 9AT, England); Cohen, G. M. *Cancer Res* 38(9): 3066-3075; 1978.

The metabolism of benzo(a)pyrene (BP) and its primary metabolites to their major ethyl acetate- and water-soluble (eas and ws) metabolites by cultured rat and hamster trachea was investigated. The major eas metabolites of BP cochromatographed with and had fluorescence excitation and emission spectra similar to 9,10-dihydrodiol, 7,8-dihydrodiol, and benzo(a)pyren-3-yl hydrogen sulfate. Enzymic hydrolysis of the ws metabolites suggested that the two major ws glucuronide conjugates were those of the monohydroxy-BP's and 4,5-dihydrodiol. Studies of the metabolism of the individual metabolites indicated that 3-hydroxy-BP was metabolized to an eas product that cochromatographed with and had fluorescence excitation and emission spectra similar to benzo(a)pyrene-3-yl hydrogen sulfate and to a ws glucuronide conjugate. 4,5-Dihydrodiol was metabolized to an unidentified eas metabolite and to a ws glucuronic acid conjugate. Both 7,8-dihydrodiol and, to a smaller extent, 9,10-dihydrodiol were metabolized, presumably via their respective diol-epoxides, to an eas metabolite that cochromatographed with and had fluorescence excitation and emission spectra similar to 7,8,9,10-tetrahydro-7,8,9,10-tetrahydroxy-BP. However, significant differences were observed in the ws metabolites formed from these metabolites. A major pathway of 7,8-dihydrodiol metabolism was to its ws glucuronide conjugate, but little or no 9,10-dihydrodiol was conjugated directly with uridine diphosphate glucuronic acid (UDGA). Small amounts of 9,10-dihydrodiol were metabolized to the catechol 9,10-dihydroxy-BP, which was rapidly conjugated with UDGA. These findings indicate that the rodent trachea, an area susceptible to hydrocarbon carcinogenesis, can metabolize BP to a wide range of oxidative and conjugative products. Factors affecting the balance and activities of these enzyme systems may be important in determining the susceptibility of the respiratory tract to carcinogenesis. (59 refs.)

78-4343 **Toxicity and Carcinogeniciy of Benzo(a)pyrene on Lung Cell Cultures and Cultivated Tracheal Tissue of Fetal Syrian Gold Hamsters. The Development and First Experiences with an in Vitro Test System.** (Ger) Richter-Reichhelm, H. B. (Hannover, W. Germany); Emura, M. *Staub-Reinhalt Luft* 38(6): 247-250; 1978.

Mixed lung cell cultures from Syrian gold hamster embryos (15 days gestation) were treated with varying concentrations of benzo(a)pyrene (BP). A dose-dependent toxicity was observed in the colony-forming assay. The addition of insulin (0.2 IU/ml)to the culture medium increased the plating efficiency of the cells from 1% to 3.9%. The colonies were divided into fibroblast, epi-, and endotheliallike cells. The toxicity of BP for these cells was also dose-dependent. BP-induced transformation rates were determined in the fibroblastic cells and were shown to be dose-dependent. At 0.05 and 0.25 μg BP the transformation rate was 1%, but at other doses 0.5% was never attained. Increases in insulin content increased BP toxicity in transformed fibroblasts. In soft-agar tests performed to detect the transformation of the epi- and endotheliallike cells, 4/6 cell lines had colony-forming ability. Sc implantation of 5 x 10^6 of these cells into syngenetic neonates resulted in walnut-sized sarcomas in 4/5 animals over a 3-mo period. The histological evaluation of BP treated in vitro explants of tracheal tissue from the same fetuses is in progress. Observations on 66% of the explants treated with 0.75 μg BP indicate that approx 15% show squamous metaplasia and other epithelial alterations. (6 refs.)

78-4344 **In Vitro Cell Transformation of Hamster Renal Cells Under the Influence of Atmospheric Fine-dust Extracts and the Papovavirus SV40.** (Ger) Seemayer, N. (Dusseldorf, W. Germany). *Staub-Reinhalt Luft* 38(6): 254-258; 1978.

The carcinogenic effects of fine atmospheric dust extracts were examined in Syrian gold hamster renal cells that were vaccinated with simian virus 40 (SV40) (Line Rh 911). Carcinogenic polycyclic hydrocarbons including: benzo(a)pyrene, 9,10-dimethylbenzanthracene, and dibenz(a,h)anthracene, each dissolved in a 0.5-1 mg/ml soln of dimethyl sulfoxide, were tested on the same system. The fine atmospheric dust extracts caused a significant increase in the transformation rate of cultures of SV40-inoculated hamster renal cells. There was also a significant increase in the transformation rate after exposure to the carcinogenic polycyclic hydrocarbons. The test system using hamster renal cells enables a clear differentiation of normal cells from transformed cells due to typical morphology and newly acquired immunologic characteristics. The atmospheric dust extracts seem to contain substances that increase the SV40 induced transformation rate. The mechanism for this increased rate remains unclear, but the polycyclic hydrocarbons contained in the extracts are implicated. (20 refs.)

78-4345 **Carcinogenic Atmospheric Pollutants and the Nature of Low-Level Risks.** (Eng) Albert, R. E. (Inst. Environmental Medicine, New York Univ. Medical Center, New York, NY, 10016); Burns, F. J. *In: Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation.* Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 289-292; 1977.

Air pollution carcinogenesis studies suggest that extrapolation of dose-tumor incidence curves to define a probability of developing cancer from a given low-level of carcinogen exposure are inaccurate in the absence of knowledge about concomitant exposure to promoting agents. Low-level carcinogen exposure may heighten the susceptibility to cancer induction by otherwise noncarcinogenic substances. (8 refs.)

78-4346 **Study on Some Aspects of Exhaust Emissions from Diesel Engines.** (Eng) Srinivasa Rao, P. S. (I.C. Engines Lab. Dept. Mechanical Engineering, Indian Inst. Technology, Madras-600 036, India); Gopalakrishnan, K. V.; Murthy, B. S. *Chem Age India* 28(12): 1143-1145; 1978.

Studies were made of the cause of excessive smoke emissions from diesel-powered vehicles, effectiveness of antismoke fuel additives, effect of a dual fuel system using ethylalcohol and diesel fuel on pollution from diesel engines, and the effect of operating conditions on exhaust levels of nitric oxide and benzo(a)pyrene. (2 refs)

78-4347 **Differences in Effects of Norharman with Various Classes of Chemical Mutagens and Amounts of S-9.** (Eng) Nagao, M. (Biochemistry Div., Natl. Cancer Center Res. Inst., Tsukiji 5-1-1, Chuo-ku, Tokyo 104, Japan); Yahagi, T.; Sugimura, T. *Biochem Biophys Res Commun* 83(2): 373-378; 1978.

The effect of norharman on the mutagenicity of various chemicals depends on the class of chemical and on the amount of S-9 mix (metabolic activation system prepared from rat liver). For example, aniline was mutagenic only in the presence of norharman, and mutagenicity increased linearly with the amount of S-9 mix. Norharman also increased the mutagenicity of benzo(a)pyrene in the presence of a large amount of S-9 mix but suppressed its mutagenicity when small amount was used. (17 refs.)

78-4348 **The Relationship Between Carcinogenicity an Mutagenicity of Some Polynuclear Hydrocar bons.** (Eng) Andrews, A. W. (Chemical Carcinogenesis Pro gram, Frederick Cancer Res. Center, Frederick, MD, 21501) Thibault, L. H.; Lijinsky, W. *Mutat Res* 51(3): 311-318; 1978

Ten polynuclear hydrocarbons and 15 of their partially hydrogenated derivatives were tested for mutagenicity using th Ames *Salmonella typhimurium* assay, and the results wer compared with existing carcinogenicity data. Only 1/25 compounds was mutagenic when tested in the absence of the Aroclor 1254-stimulated liver microsome S-9 mix. The remainde were mutagenic in at least one strain of *Salmonella* whe activated by a crude microsomal preparation from rat liver Of the 24 compounds that have been tested for carcinogenicity, there was a correlation between mutagenicity in the Ame system and carcinogenicity for 14. Eight of the remainin compounds were false positives and two were false negative in the Ames assay. This does not preclude acceptance of th basic precept of the Ames test as a good one, and its effectiveness in predicting carcinogenicity might be increased in th future. (14 refs.)

78-4349 **Seasonal Variation of Aryl Hydrocarbon Hydroxylase Inducibility in Human Lymphocytes in Culture.** (Eng) Richter, A. (Dept. Pharmacology, Univ. Toronto, Toronto, Ontario, Canada, M5S 1A8); Kadar, D.; Liszka-Hagmajer, E.; Kalow, W. *Res Commun Chem Pathol Pharmacol* 19(3): 453-475; 1978.

The aryl hydrocarbon hydroxylase (AHH) inducibility in lymphocytes from the peripheral blood of 92 healthy subjects (19-39 yr old) was tested during an 8-mo period (November-June). The av AHH inducibility was higher from March to June than from November to February, indicating a seasonal variation. The absolute number of lymphocytes was generally increased during May and June, resulting in an increased number of cells started in culture. However, a qualitative change within the lymphocyte population appeared to have taken place earlier (in March and April), resulting in an exceptionally high recovery rate of cells after 96 hr in culture; this change was associated with a higher av AHH inducibility in these months than in other months. The increased number of lymphocytes in blood observed in May and June was associated with only a minor increase in their AHH inducibility, compared with AHH inducibility during late fall and winter. Regardless of the cause of the change in AHH inducibility during different periods of the year, ignoring the change may produce an error in assessing the distribution of AHH inducibility among the population. (46 refs)

78-4350 **Aryl Hydrocarbon Hydroxylase Inducibility and Carcinoma of the Urinary Bladder.** (Eng) Trell, E. (Section Preventive Medicine, Univ. Lund, Lund, Sweden); Oldbring, J.; Korsgaard, R.; Hellsten, S.; Mattiasson, I.; Telhammar, E. *IARC Med Sci [Cancer]* 6(4): 138; 1978.

Aryl hydrocarbon hydroxylase (AHH) inducibility was assessed in 46 patients with carcinoma of the urinary bladder. Six had high inducibility levels, 18 intermediate, and 22 low. In the male patients, but not in the female patients, there was an overrepresentation of tobacco consumers. The AHH inducibility distribution did not differ from that of normal populations. There were no differences according to sex and age of the patients, smoking habits, type of cancer (recidivating or nonrecidivating, transitional or flat epithelial), or hereditary or occupational history. The findings support previous conclusions that high AHH inducibility plays no significant role in the pathogenesis of urinary bladder carcinoma. (16 refs)

78-4351 **Embryopathies Due to Spermatozoal Impairment in Xenopus Laevis.** (Eng) Hemsworth, B. N. (Life Science Lab., Teesside Polytechnic, Middlesbrough, Cleveland, England); Wardhaugh, A. A. *Mutat Res* 51(1): 45-53; 1978.

The effects of γ-radiation and various chemicals, including a range of contraceptive steroids, on the spermatozoa and developing embryos of the toad *Xenopus laevis* were studied. Sperm motility and the number of ova cleaved were reduced by exposure of the sperm to dimethylmyleran, trimethylphosphate (TMP), α-chlorohydrin, various progestational steroids, and the estrogenic steroids ethinyl estradiol and mestranol. Methyl methanesulfonate (MMS) had no apparent effect on sperm motility of fertilizing capacity, but it was cytotoxic to sperm. γ-Rays had no adverse effects on sperm motility or fertilizing ability. Exposure to either of the isomeric forms of dimethylmyleran, MMS, or γ-radiation led to a significant production of deformed tadpoles, whereas TMP, α-chlorohydrin, the progestational steroids, and the estrogenic steroids had no embryopathic effects. These findings provide some reassurance regarding the possible mutagenic action of oral contraceptives. (19 refs.)

78-4352 **Hepatocellular Carcinoma in a Young Woman with Prolonged Exposure to Oral Contraceptives.** (Eng) Gattanell, P. N. (Dept. Neoplastic Diseases, Mount Sinai Sch. Medicine, 100th St. and Fifth Ave., New York, NY, 10029); Perloff, M.; Holland, J. F. *Med Pediatr Oncol* 4(2): 99-103; 1978.

A case of hepatocellular carcinoma in a 28-yr-old woman is presented in which the apparent etiology was the use of oral contraceptives for 5.5 yr. Her total calculated dose was 1,365 mg of norethindrone, the 17,α-ethinyl-substituted derivative of 19-nortestosterone, and 68 mg of mestranol, the 3-methyl ether of ethinylestradiol. There was no history of hepatitis or alcoholism. Sequential therapeutic trials with ia 5-fluorouracil, ia adriamycin, and iv 1,3-bis(2-chloroethyl)-1-nitrosourea were unsuccessful. The patient died in hepatic coma 8 mo after diagnosis. She never became jaundiced or developed ascites, and the bilirubin level never rose above 2 mg/dl. This is the eighth report of hepatocellular carcinoma in women of childbearing age treated with oral contraceptives. (28 refs.)

78-4353 **Hormonal Factors Related to the Incidence of Testicular Tumors in Male Pseudohermaphrodite Rats.** (Eng) Allison, J. E. (P.O. Box 26901, Univ. Oklahoma Health Sciences Center, Oklahoma City, OK, 73190); Weidenbach, P. W.; Becker, R. R.; Hollander, R. *Fertil Steril* 30(1): 91-95; 1978.

A study was undertaken to determine if testicular tumors in male pseudohermaphrodite (tfm) rats were hormone-dependent and, if so, which hormone(s) was involved. Pieces of testicular tumor from tfm rats were transplanted into the connective tissue between the skin and the body wall musculature of the groins of normal males and females and tfm males. Pieces were also transplanted to the anterior chambers of the eyes of intact and gonadectomized normal males and females, and intact and gonadectomized tfm males. The transplants grew in all hosts except normal males. Levels of circulating gonadotropins were measured in all host types. All hosts except normal males had high serum levels of luteinizing hormone (LH), indicating that testicular tumors in tfm rats are LH-dependent. Since the anatomical, genetic, endocrinologic conditions in tfm rats are similar to those in human patients with testicular feminization, this LH dependence may also be true in man. (13 refs.)

78-4354 **Plutonium-239 Deposition in the Skeleton of the Mouse.** (Eng) Green, D. (MRC Radiobiology Unit, Harwell, Didcot, Oxfordshire, OX11 0RD, England); Howells, G. R.; Thorne, M. C. *Int J Radiat Biol* 34(1): 27-36; 1978.

The distribution, 24 hr later, of iv injected plutonium-239 in the skeleton of the female CBA mouse was investigated by neutron-induced autoradiography together with computer-based methods of data reduction. With these techniques, it was possible to measure the localization of ^{239}Pu on the endosteal and periosteal surfaces of the bone to an accuracy of approx ± 2.5 μm. At 24 hr after injection, distribution of ^{239}Pu about the endosteal and periosteal surfaces of the third lumbar vertebra, a central caudal verebra, the right ilium, and the right femur was similar except for the endosteal surfaces of the ilium. Except for the latter, $>$ 60% of the ^{239}Pu lay within the bone, some penetrating as fas as 20 μm into the bone. In the ilium, the distribution was more strongly peaked about the edge of the bone image. Although the distribution on various bone surfaces appeared similar, the absolute magnitude of deposition varied from one bone to another, as shown by radiochemical analyses of ^{239}Pu in other comparable bones of the skeleton. It is assumed that ^{239}Pu deposition in bone is influenced more by extrinsic features such as blood supply than by the particular nature of the local bone surface. (14 refs.)

78-4355 **The Uptake and Redistribution of ^{241}Pu Within the Gonads.** (Eng) Priest, N. D. (Natl. Radiological Protection Board, Harwell, Didcot, Oxfordshire, England); Jackson, S. *Int J Radiat Biol* 34(1): 49-65; 1978.

The distribution pattern and binding sites of plutonium in the testes and ovaries were studied following the iv administration of ^{241}Pu citrate soln to male and female hamsters and a female rabbit. Within the first 2 hr after injection, marked concentrations of β tracks were associated with a small number of atretic graafian follicles and with the follicular fluid in the thecal rings of the ovaries. One day after injection, most of the plutonium in the atretic follicles was phagocytosed by macrophages, and after 10 days, β tracks were most conspicuous over macrophages in the stroma and ovarian medulla, with little plutonium remaining in the atretic follicles. β Tracks were seen throughout the testes 15 min and 2 hr after injection, possibly because of an artifact of tissue processing. After 1 day and, to a greater extent, after 10 days, there was a focalization of β tracks in the cells comprising the interstitial tissue. It appeared that the macrophages had accumulated the plutonium in this tissue. No migration of macrophages was seen in the testes. Histochemical staining revealed the presence of acid protoglycans, including chondroitin sulfate and glycoproteins at the sites of plutonium concentration i the ovary. These molecules were regarded as likely recepto sites for plutonium. No acidic carbohydrates were found i the testes, in which the initial binding site for plutonium ma be a compound lipid. This was deduced from the apparen inability of the interstitial tissue of the testes to bind plutoni um in situ. (17 refs.)

78-4356 **A Mathematical Model for Estimation o Plutonium in the Human Body from Urine Dat Influenced by DTPA Therapy.** (Eng) Hall, R. M. (E. I. du Pont Co., Savannah River Plant, Aiken, SC, 29801); Poda G. A.; Fleming, R. R.; Smith, J. A. *Health Phys* 34(5) 419-431; 1978.

An empirical model for the urinary excretion of plutoniu (Pu) was developed using bioassay data from accidentally exposed patients (two puncture wound cases and several inhalation cases) treated with diethylenetriaminepentaaceti acid (DTPA). The mathematical expressions derived included functions relating the fraction of systemic Pu available fo chelation to the time of the initial deposition and the interva between successive treatments. These empirical expression can be used to provide an early assessment of systemic burdens for DTPA-treated patients, for determining the optima DTPA dosage regimen, and for evaluating the effectivenes of DTPA therapy. DTPA therapy initiated immediately afte Pu contamination will reduce the body burden by a facto of about 30. A larger fraction of Pu loosely deposited in bod tissues can be removed by prolonged therapy. A recent P inhalation incident was used to demonstrate the usefulnes of this model for early assessment of a worker's systemi burden from urinary excretion data during extended DTPA therapy. Pu urinary excretion data for six workers were compared with the excretion rates predicted by the Pu-DTPA model and a reasonably good correlation was obtained. (2 refs.)

78-4357 **^{32}P and Acute Leukemia: Development of Leukemia in a Patient with Hemoglobin Yakima** (Eng) Bagby, G. C. (Leukemia Res. Lab., VA Hosp., Portland, OR, 97207); Richert-Boe, K.; Koler, R. D. *Blood* 52(2) 350-354; 1978.

Acute nonlymphocytic leukemia (ANLL) developed in 197 in a 54-yr-old man who had been treated with ^{32}P for polycythemia vera (PV), which was diagnosed in 1954. He had re ceived ^{32}P at intervals of 6-24 mo over a period of 10 yr (1955-1965) to a cumulative dose of 72 mCi. In 1964, his daughters were found to have erythrocytosis. Investigation led to the discovery in all three patients of a new Hb variant, Hb Yakima, with high oxygen affinity. After ^{32}P therapy was discontinued, the man remained stable until 1975, when he developed pancytopenia and a progressive increase in HbF. In 1976, peripheral blood and bone marrow samples supported the diagnosis of the preleukemic syndrome. One year later, the patient developed ANLL accompanied by fetal erythropoiesis. Because this type of hemoglobinopathy was discovered 27 yr after the introduction of ^{32}P for the treatment of PV and because there are now > 39 high-oxygen-affinity Hb's, it is anticipated that additional patients similar to the one reported have been exposed to ^{32}P. These patients may be the first group to permit assessment of the risk of ^{32}P-induced leukemia in a non-neoplastic disorder. (20 refs.)

78-4358 **Investigation of Tritium Incorporation by Means of Excreted Metabolites.** (Eng) Biro, T. (Inst. Isotopes, 1525 Budapest, pf. 77, Hungary); Szilagyi, M. *Curr Top Radiat Res* 12(1): 313-321; 1977.

Daily urine samples from workers repeatedly exposed to ^{3}H during the chemical processing of various labeled compounds were analyzed by liquid scintillation counting. ^{3}H concentrations were determined in native or treated (charcoal and/or acid) urine and in the urea, creatinine, protein, and centrifuge residue fractions. The time dependence of ^{3}H concentrations in the urea and in the centrifuge residue differed significantly from that of the ^{3}H in native or treated urine. In the urea fraction, the ^{3}H half-life was about 20 hr. (16 refs)

78-4359 **Unusual Dose-Response of Chromosome Aberrations Induced in Human Lymphocytes by Very Low Dose Exposures to Tritium.** (Eng) Hori, T. A. (Div. Genetics, Natl. Inst. Radiological Sciences, 9-1, 4-Anagawa, Chiba 280, Japan); Nakai, S. *Mutat Res* 50(1): 101-110; 1978.

WBC cultures prepared from the peripheral blood of a healthy adult man were exposed for 48 hr to tritiated water or ^{3}H-thymidine (^{3}H-TdR), at doses ranging from 1×10^{-3} to 100 μCi/ml. Aberrations in the lymphocyte chromosomes were examined in the metaphase figures accumulated during a 5-hr treatment with colcemid. A low level of DNA synthesis was found as early as 24 hr after exposure to tritiated water or ^{3}H-TdR. However, the DNA labeling index increased continuously, and it reached a level of 20% at 48 hr. The aberrations induced by the radiation from both sources were mostly chromatid types, such as chromatid gaps and deletions. The dose-response relationships produced unusual curves in both cases. At the higher dose range, the yields of chromatid breaks increased linearly with dose, but those at the lower dose range were significantly higher than would be expected by downward extrapolation from the linear relation. Partial-hit or partial-target kinetic events occurred at the very low dose levels (lower than 5 and 5×10^{-2} μCi/ml for tritiated water and ^{3}H-TdR, respectively). (24 refs)

78-4360 **Problems of Extrapolation from High Dose to Low Dose in *Tradescantia* Mutation Studies.** (Eng) Nauman, C. H. (Biology Dept., Brookhaven Natl. Lab., Upton, NY, 11971); Sparrow, A. H. *Environ Health Perspect* 22: 161-162; 1978.

Problems in extrapolating the effects of low-dose carcinogen exposure from those of high-dose exposure were studied by treating inflorescences of several clones of *Tradescantia* with ionizing radiation and with the gaseous form of several known or suspected chemical mutagens. The dose rate at which a radiation dose-response curve was determined was found to have a significant influence on any downward extrapolation: the lower the dose rate, the closer the curve would approach a +1 slope and the more accurately would an extrapolation to lower doses predict the mutagenicity in that low-dose region. Slopes of the exposure-response curves obtained after exposure of three clones to gaseous 1,2-dibromoethane (DBL) and ethyl methanesulfonate (EMS) varied from +0.6 to +2.4. In one clone, 250 ppm EMS was four times as mutagenic as 160 rads of acute x-rays. For DBE, slopes generally increased from +1 to +1.5 as exposure time increased from 2 hr to 6 days. Since there was some indication that the slope may decrease at low exposure, extrapolation of high exposure data to low-exposure situations might give an underestimation of the danger of a low exposure to DBE. (no refs)

78-4361 **Low-Dose Radiation (Letter to Editor).** (Eng) Kneale, G. (Regional Cancer Registry, Queen Elizabeth Hosp., Birmingham 15, England); Stewart, A. M. *Lancet* 2(8083): 262-263; 1978.

In 1944-1972 and 1944-1977 studies of cancer deaths among Hanford nuclear plant workers, the low risk estimates found, in the form of doubling doses (in rads) are defended. Questions are raised as to whether some widely held assumptions about the role of radiation in carcinogenesis can be applied to the Hanford data. It was found that all ionizing radiations are not sufficiently similar for similar values of doubling dose to apply, that all members of a population are not equally sensitive to radiation, that sensitivity to radiation varies with age, and that the dose-response relationship in this case would not be linear. Comparison of observed and expected cancer deaths can show if there is a cancer hazard for nuclear industry workers, but the dose levels should be higher than those in the Hanford study (mean cumulative dose was 1.38

rads for cancers, 0.99 for noncancers). However, it is significant that the mean cumulative dose was higher for 22 bone marrow cancers (4.49 rads) than for 42 other reticuloendothelial neoplasms (0.99 rads), even though these two groups accounted for only 3.3% and 6.3% of the fatal cancers (expected proportions, 2.0% and 8.6%). (5 refs.)

78-4362 **DNA-Repair after UV-Irradiation in Skin Fibroblasts from Patients with Actinic Keratosis.** (Eng) Sbano, E. (Dept. Dermatology, Univ. Siena, Siena, Italy); Andreassi, L.; Fimiani, M.; Valentino, A.; Baiocchi, R. *Arch Dermatol Res* 262(1): 55-61; 1978.

An autoradiographic counting technique was used to measure UV-induced unscheduled DNA synthesis in skin fibroblasts from 12 patients with chronic actinic keratosis (AK) and those from 12 aged-matched healthy controls. Fibroblast cell strains were obtained from the forehead skin and the abdominal or axillary skin of each subject. Skin fibroblasts from the AK patients showed a lower level of excision repair of UV-induced DNA damage than fibroblasts from normal subjects. In both normal subjects and AK patients, fibroblasts from skin ordinarily exposed to sunlight showed a higher DNA repair capacity than did fibroblasts from normally unexposed skin. DNA repair decreased as a function of aging in both groups of subjects. The data show that skin cancer DNA in AK patients may be promoted by a defect in DNA repair. The increased repair capacity of skin that is chronically exposed to sunlight is probably the consequence of a defensive process caused by enzymatic induction. (14 refs.)

78-4363 **Induction of Ouabain-resistant Mutations in C3H 10T1/2 Mouse Cells by Ultraviolet Light.** (Eng) Chan, G. L. (Lab. Radiobiology, Dept. Physiology, Harvard Univ. Sch. Public Health, Boston, MA, 02115); Little, J. B. *Proc Natl Acad Sci USA* 75(7): 3363-3366; 1978.

Ouabain-resistant mutants were induced in C3H mouse embryo 10T1/2 fibroblasts by exposing them to UV light, thus making available an in vitro system for studying mutagenesis and oncogenic transformation in parallel. ^{86}Rb uptake studies showed that biochemical mutants at the plasma membrane Na+,K+ transport ATPase locus were being selected for in this system. The optimal expression time for the mutants and the induced mutation frequency depended on the dose of UV light. The ratio of transformation to mutation frequencies was on the order of 10 for four different doses (25, 50, 75, and 100 ergs/mm^2, which suggests that the target size in the cellular genome for transformation may be approx 10 times the size of the Na+,K+ ATPase gene. It is proposed that both transformation and mutation induction can be quantitatively studied in this single system. (39 refs.)

78-4364 **Damage and Repair in Mammalian Cells after Exposure to Non-ionizing Radiations. I. Ultraviolet and Visible Light Irradiation of Cells of the Rat Kangaroo (*Potorous Tridactylus*) and Determination of Photorepairable Damage In Vitro.** (Eng) Harm, H. (Programs in Biology, Univ. Texas at Dallas, P. O. Box 688, Richardson, TX, 75080). *Mutat Res* 50(3): 353-366; 1978.

Cornea cells of the rat kangaroo (potoroo, *Potorous tridactylus*) were exposed to far-UV [254 or 302 nanometers (nm)] radiation with or without subsequent illumination by near-UV or visible light, and the cellular DNA was tested for the presence of photoproducts binding yeast photoreactivating enzyme (PRE). DNA from untreated control cells contained no binding sites for the yeast PRE. The DNA of far-UV-irradiated cells kept in the dark prior to DNA extraction showed considerable competitive inhibition (CI) of the in vitro photorepair system, which consisted of UV-irradiated transforming DNA of *Haemophilus influenzae* and an extract containing yeast PRE. When the irradiated cells were exposed to white light prior to DNA extraction, the CI by their DNA was much reduced. An initial irradiation of 254 or 302 nm produced similar results. In further experiments, potoroo cells were exposed for various time periods to 0.18% hydrogen peroxide. Increasing time of pretreatment with H_2O_2 was associated with increasing CI of the in vitro photorepair system by the DNA extracted from the cells; similar results were obtained when the extracted DNA only was treated with H_2O_2. CI by irradiated potoroo DNA was reduced by exposure to wavelengths $>$ 470 and $>$ 415 nm, but not to wavelengths $>$ 555 or $>$ 365 nm. Even the wavelengths with the best photorepair effectiveness caused some damage, interacting with the yeast PRE in vitro. For unknown reasons, one particular strain of potoroo cells lost its potential for photorepair. The data suggest that the expression of photorepair in mammalian cells depends on a number of experimental parameters, including the spectral composition of the photoreactivating light. Superposition of damage by the photoreactivating treatment appears to be the critical factor. (21 refs.)

78-4365 **Toxicity and Mutagenicity of Radiation from Fluorescent Lamps and a Sunlamp in L5178Y Mouse Lymphoma Cells.** (Eng) Jacobson, E. D. (Bureau Radiological Health, HFX 120, 5600 Fishers Lane, Rockville, MD, 20857); Krell, K.; Dempsey, M. J.; Lugo, M. H.; Ellingson, O.; Hench, C. W. *Mutat Res* 51(1): 61-75; 1978.

The toxic and mutagenic effects of the broad-spectrum light from several types of fluorescent lamps and from a mercury vapor sunlamp were studied in L5178Y mouse lymphoma cells. To facilitate comparison of the different rates of mutagenesis derived from exposure-reponse curves obtained for each light source, a parameter, joule-equivalent mutagenesis (jem), equal to mutants per 10^5 survivors per joule per square meter, was defined. Jem values were calculated using the integrated irradiance of each lamp. Unfiltered broad-spectrum radiation emitted by germicidal, mercury vapor, black light blue, black light, and cool white lamps was both toxic and mutagenic to L5178Y cells when the cells were irradiated in phosphate-buffered saline. Based on jem values, the relative mutagenicities of the lamps (compared with the germicidal UV lamp) were 3×10^{-3} for the sunlamp, 1×10^{-4} for the black light and cool white lamps, and 3×10^{-5} for the black light blue lamp. The mutagenic effect was linear throughout the range of exposures tested, and the toxic and mutagenic effects of the lamps were in general agreement with their relative spectral outputs from 290 to 330 nanometers. (19 refs.)

78-4366 **Induction of Cancer by Photodynamic Action and the Problem of Benefits and Potential Risk in Photochemotherapy in Humans.** (Eng) Santamaria, L. (Camillo Golgi Inst. General Pathology, Univ. Pavia, Pavia, Italy); Giordano, G. G. *In: Characterization and Treatment of Human Tumours. Proceedings of the Seventh International Symposium on the Biological Characterization of Human Tumours held in Budapest, April 13-15, 1977.* Davis, W.; Harrap, K. R., eds. (Amsterdam: Excerpta Medica): Advances in Tumour Prevention, Detection and Characterization. Vol. 4, 332 pp.; 146-150; 1978.

The hypothesis that a photodynamic reaction can be carcinogenic whenever the damage at the molecular level is still compatible with cellular life but is able to bring about neoplastic transformation was investigated by exposing 955 Swiss albino mice to benzo(a)pyrene (BP) and Wood's 125-watt light. In the first experiment, groups of mice were exposed to Wood's light (2x/wk for different lengths of time) and/or painted with BP. A tumor incidence of 4% was noted in BP-treated mice, but the highest incidence (58%) was noted in mice treated with BP and exposed to the light (8×10^{10} ergs/cm^2, not the highest dose used). In another experiment, two groups of mice were exposed to Wood's light and two groups were kept in rooms illuminated by daylight or kept in darkness. Mice receiving Wood's light developed carcinomas earlier than those kept in the dark, but continued irradiation inhibited carcinoma formation. Daylight accelerated carcinoma onset, which led to an increase in carcinoma incidence in these mice over that in mice kept in the dark. A third experiment was conducted along the lines of the first using a light dosage of 8×10^{10} ergs/cm^2. Light exposure resulted in a max 70% increase in benign and approx 100% increase in malignant neoplasms. At the molecular level, it is assumed that the induction of cancer by BP and light is due to a mutagenic effect. The observation of enhancement and inhibition of carcinogenesis, depending on the extent of light exposure (also noted in in vitro experiments), suggests that carcinogenesis and its enhancement by photodynamic action might be consistent with a cellular damage compatible with cellular life, whereas inhibition of carcinogenesis by photodynamic action should occur when the damaging effects kill normal as well as malignant or potentially malignant cells. Although the long-term effects of photodynamic treatment in humans are not known, the clinical benefits appear to depend on the death of the affected cells rather than their recovery after inactivation of the infectious agents. (45 refs.)

78-4367 **A Vitamin A Analogue Inhibits Radiation-induced Oncogenic Transformation.** (Eng) Harisiadis, L. (Radiological Res. Lab., Coll. Physicians and Surgeons of Columbia Univ., New York, NY, 10032); Miller, R. C.; Hall, E. J.; Borek, C. *Nature* 274(5670): 486-487; 1978.

The possibility that retinoids might inhibit radiation-induced oncogenic transformation was studied using cultured C3H mouse embryo fibroblasts. The transformation frequency following a single dose of ^{60}Co γ rays (400 rads) was determined in the presence and absence of the trimethylmethoxyphenyl analog of N-ethylretinamide (Ro-11-1430: 7.1 μM. The retinoid was not toxic at the concentrations used, and it significantly reduced the transformation rate from 9.04×10^{-4} transformants/surviving cell to 2.67×10^{-4}. Preliminary experiments indicated that much higher retinoid concentrations reduced the transformation rate near zero; however, some toxicity was observed at these concentrations. Ongoing experiments with other vitamin A analogs suggest that the ability to inhibit radiation-induced transformation is not confined to Ro-11-1430. Retinoids could have a role in the prevention of neoplasms induced by radiation as well as by chemical carcinogens. (18 refs.)

78-4368 **Occurrence of Carcinogenesis and Leukemogenesis Following Diagnostic and Therapeutic Exposure to Ionizing Radiation.** (Ger) Neumeister, K. (Staatliches Amt fur Atomsicherheit und Strahlenschutz der DDR, Waldowallee 115, DDR-1157 Berlin, E. Germany). *Dtsch Gesundheitsw* 32(38): 1793-1796; 1977.

Two men and two women who had been exposed to diagnostic, therapeutic, or occupational ionizing radiation developed squamous epithelial carcinomas at the irradiation site. The first patient had received repeated x-radiation for tinea barbae 42 yr before he developed keratinizing squamous epithelial carcinoma of the cheek. One irradiation session was longer than planned, but the total dose could not be established. Another patient received pelvic x-ray therapy (total dose 3,000 rads) after ovariectomy for benign cystadenoma of the ovaries. She developed a radiation ulcer and, finally, carcinoma 23 yr later. A third patient developed keratinizing squamous epithelial carcinoma 17 yr after removal of a broken needle from her hand with the aid of fluoroscopy. The dose rate was estimated to be 20 R/min. A surgeon who had been exposed to ionizing radiation occupationally prior to 1945 developed typical radiogenic lesions of his hands and ultimately, keratinizing squamous epithelial carcinoma of the index finger. The dose could not be estimated. A causative relationship between prior exposure to ionizing radiation and carcinoma is possible in all cases. (41 refs.)

78-4369 **Pituitary Fibrosarcoma Secondary to Radiation Therapy.** (Eng) Ahmad, K. (Dept. Radiology, Alice Crocker Lloyd Radiation Therapy Center, Univ. Hosp., 1405 E. Ann St., Ann Arbor, MI, 48109); Fayos, J. V. *Cancer* 42(1): 107-110; 1978.

A 56-yr-old man who received postoperative radiation therapy for a chromophobe adenoma developed a fibrosarcoma of the pituitary gland region 10 yr later. A total dose of 4,092 rads of cobalt-60 radiation was applied to the pituitary in a single course of 21 fractions over 29 days. (7 refs)

78-4370 **Hyperparathyroidism and Radiation Therapy.** (Eng) Christensson, T. (St. Eriksplan 2A, S-11320 Stockholm, Sweden). *Ann Intern Med* 89(2): 216-217; 1978.

The association of hyperparathyroidism (HPT) and previous radiation therapy to the neck was investigated among a group of 15,903 persons who entered a medical screening program in Stockholm, Sweden. Hypercalcemic HPT with parathyroid adenomas was discovered in 58 people (44 women, 14 men). The adenomas were single in all but a few patients. In no case was parathyroid hyperplasia found. All patients underwent exploration because of constant hypercalcemia upon repeated testing. Postoperative serum calcium values were normal. The 44 patients plus age- and sex-matched controls randomly chosen from the screening program group were investigated with respect to prior radiation therapy. Eight women in the hyperparathyroid group had received neck irradiation vs none of the controls. The eight patients had been irradiated at a mean age of 8.1 yr, and their mean age at diagnosis of HPT was 55.2 yr. All had been irradiated with x-rays (200-600 rads) for tuberculous adenitis. This study confirms that a relation exists between radiation therapy to the neck and the development of HPT. (14 refs.)

78-4371 **Synovial Sarcoma of the Neck Associated with Previous Head and Neck Radiation Therapy.** (Eng) Mischler, N. E. (Quisling Clinic, 2 W. Gorham St., Madison, WI, 53703); Chuprevich, T.; Tormey, D. C.; Ramirez, G.; Mack, E. A. *Arch Otolaryngol* 104(8): 482-483; 1978.

The case report of a 28-yr-old man who developed a synovial sarcoma in his neck 14 yr after receiving four facial and neck irradiation treatments for acne is presented. The total radiation dose that had been delivered was not known. Special stains and electron microscopy disclosed a characteristic synovial sarcoma. Ten months after surgery the lesion recurred, and the patient was treated with radiotherapy and chemotherapy. The histologic appearance of the tumor suggests a synovioblastic origin: it most likely arose from undifferentiated mesenchyme that retained the potential for synovioblastic differentiation. (10 refs.)

78-4372 **Thorium-induced Neoplasia of the Spleen.** (Ger) Schumacher, K. A. (Department fur Radiologie I, Universitat Ulm, Steinhovelstrasse 9, D-7900 Ulm/Donau, W. Germany); Bargon, G. *Soobshch Akad Nauk Gruz SSR* 31(8): 486-488; 1978.

The case report of a 58-yr-old man who presented with multiple circular foci in the spleen 25 yr after application of a thorium-containing contrast medium for vascular visualization is presented. In addition to these foci, ThO_2 deposits were present in the liver and spleen. The foci met the angiographic criteria of an angioblastic sarcoma. The problem of whether the lesions are thorium-induced is discussed. (12 refs.)

78-4373 **Thorotrast as an Etiological Factor in the Development of Malignant Bone Marrow Diseases.** (Ger) Fabricius, H. A. (Medizinische Klinik der Universitat, Hugstetter Strasse 55, 7800 Freiburg, W. Germany); Heni, N.; Mobius, W.; Henrichs, H.; Arnold, H. *Inn Med* 4(2): 76-80; 1977.

The literature contains 41 cases of leukemia (34 acute, 7 chronic) in patients previously given Thorotrast (TRT: thorium dioxide in a sugar soln). The first case was published in 1954. The frequency of leukemia in TRT-treated patients is about 8/10,000, or about 10 times the usual incidence. A case involving a 64-yr-old man is reported to illustrate the difficulty in diagnosing leukemia in TRT-treated patients. The patient presented with refractory anemia, but he was in good general condition and he had no other clinical findings. Blood and bone marrow studies led to diagnoses ranging from toxic damage to myelopoiesis or preleukemia. Two weeks later his condition had deteriorated and acute myeloid leukemia was confirmed. An x-ray-positive substance thought to be TRT was found in the spleen and later in the liver and in biopsy material from the iliac crest. No clear indication for the use of TRT emerged from the patient's history. It is assumed that it was used to treat a war-wound in 1942. Because of the age of the patient, he was treated conservatively with RBC and thrombocytes. He died 4 mo later. Thorium dioxide was identified in tissues obtained at autopsy. X-rays of the liver and spleen are helpful in determining the presence of TRT. (17 refs.)

78-4374 **Does Cholecystectomy Predispose to the Development of Colorectal Cancer?** (Fre) Capron, J. P. (Clinique Medicale, Hopital Beaujon, F 92118 Clichy Cedex, France); Delamarre, J.; Canarelli, J. P.; Brousse, N.; Dupas, J. L. *Gastroenterol Clin Biol* 2(4): 383-389; 1978.

The frequency of the association of colon cancer and chole-ystectomy was determined in a retrospective study of 237 atients (Group Ia, 129 men; Group Ib, 108 women) operated n for colon cancer and 2,458 subjects (Group IIa, 1,480 men; roup IIb, 978 women) free of colon cancer at autopsy. The ge range of the two groups of men was 50-79 yr and that f the two groups of women, 40-79 yr. The frequency of holecystectomy was significantly higher ($p < 0.001$) for the omen in Group Ib (13%) than for the women in Group IIb 3.3%); no significant difference was noted between the two roups of men. In Group Ib, the frequency of cholecystecto-ny was significantly higher in patients with cancer of the ight hemicolon ($p < 0.05$) and of the rectum ($p < 0.02$) than n those with cancer of the left hemicolon. The results indi-ate that cholecystectomy, which causes changes in bile acid netabolism, could be one of the factors predisposing to the evelopment of cancer of the rectum or colon. (31 refs)

8-4375 **The Development of Mucosal Changes After Gastric Surgery for Ulcer Disease.** (Eng) Ja-unger, K. G. (Depts. Surgery and Pathology, Univ. Hosp., Jmea, Sweden); Domellof, L.; Eriksson, S. *Scand J Gastroen-erol* 13(2): 217-223; 1978.

The development of morphological changes in the body nucosa after partial gastrectomy for ulcer disease was stud-ed early (within 3 yr) after Billroth I gastrectomy in 41 pa-ients [18 with gastric ulcer (GU), 23 with duodenal ulcer DU)], early after Billroth II gastrectomy in 14 patients (4 GU, 10 DU), late (10-24 yr) after Billroth I resection in 79 atients (44 GU, 35 DU), and late after Billroth II resection n 172 patients (41 GU, 131 DU). The morphological findings n the body mucosa of the surgical and biopsy specimens were ompared. Evaluation of the six forceps biopsies taken at gas-roscopy in all patients revealed great individual variation, ot only in the degree of atrophy and chronic gastritis, but lso with regard to the presence of intestinal metaplasia. Within 3 yr after partial gastrectomy, the mucosal changes ad become advanced in both DU and GU patients, and they vere almost as severe as those found late postoperatively. Although late postoperatively there was a higher incidence f cystic dilatation of the gastric glands after Billroth II resec-ion than after Billroth I resection ($p < 0.001$), there were o other correlations between the type of anastomotic proce-ure and the mucosal changes. In addition, there were no orrelations between the mucosal changes and factors such s age, sex, or vagotomy. The results show that the increased ncidence of mucosal changes caused by partial gastrectomy s of a similar magnitude in both DU and GU patients. If hese mucosal changes lead to malignant transformation, the results may explain why stump carcinoma has previously been found with the same frequency in patients who had undergone surgery for DU and for GU. (40 refs)

78-4376 **Proflavin Photosensitization of Double and Single Stranded DNA: EPR Study of the Effect of Various Sulphur-containing Substances.** (Eng) Piette, J (Lab. General and Medical Microbiology, Univ. Liege, Sart-Tilman, 4000 Liege, Belgium); Calberg-Bacq, C. M.; Van de Vorst, A. *Photochem Photobiol* 27(4): 457-464; 1978.

The proflavin (PF)-mediated photosensitization of double-stranded calf thymus DNA and single-stranded DNA from bacteriophage ϕ x 174 was followed by electron paramagnetic resonance measurements of free-radical induction in frozen soln in the presence of oxygen. The effect of the addition of various sulfur-containing substances to the PF-DNA mixtures was studied and quantitatively expressed for definite amounts of PF bound to both DNA's. Upon irradiation with visible light, radiosensitive radicals were observed in the presence of these sulfur-containing substances. Some of them caused a decrease in the amount of peroxide radicals normally induced in the photosensitized DNA. This decrease appeared to be linked to the ability of the compounds to interact with DNA in such a way that they modified the binding of PF to DNA. Cysteine, cysteamine, cystamine, and cystine protected calf thymus DNA against the PF and light free-radical induction by 55%, 58%, 64% and 62%, respectively. Bacteriophage single-stranded DNA is also protected by the addition of cysteamine and cystamine, although to a lesser extent than calf thymus DNA. These protective effects were observed under conditions in which strong binding of the dye to the DNA was predominant. (38 refs)

78-4377 **The Crucial Role of DNA Double-strand Breaks in Cellular Radiobiological Effects.** (Eng) Leenhouts, H. P. (Assoc. Euratom-ital, Wageningen, Netherlands); Chadwick, K. H. *Adv Radiat Biol* 7: 55-101; 1978.

A molecular theory was developed to explain the biological effects of ionizing radiation on living eukaryotic cells. An attempt was made to show that the dose relationships of the different radiation-induced effects in these cells can all be analyzed and related to the number of DNA double-strand (ds) breaks induced in the cell. It is proposed that each radiation-induced ds break has a probability of leading to cell death, chromosomal aberration, somatic mutation, malignancy, or hereditary effects. Linear-quadratic dose kinetics for the induction of ds breaks were combined with the random distribution of the number of ds breaks in a cell population to produce a series of relatively simple equations that describe the dose-response relationships for the various effects. The dose relationships are defined essentially by two coefficients, but these coefficients are made up of different parameters to take into account the complicated processes involved in the radiation interaction. The theoretical approach to mutations was extended to radiation-induced malignancy by using the results of previous investigators showing that the induction of malignancy is associated with a somatic mutation. They concluded that the factor controlling the malignant nature of a cell is contained in a chromosome and that this factor can be suppressed by the presence of a normal homologous chromosome; ie, it is recessive. In a cell carrying the recessive malignant genotype, a mutation or aberration in the normal homologous chromosome could remove the suppressive action of this chromosome and allow the expression of the malignant factor. 78-4378 **Xeroderma Pigmentosum Fibroblasts of the D Group Lack an Apurinic DNA Endonuclease Species with a Low Apparent Km.** (Eng) Kuhnlein, U. (Dept. Biophysics, B. C. Cancer Foundation, Vancouver, B. C., Canada V5Z 3K3); Lee, B.; Penhoet, E. E.; Linn, S. *Nucleic Acids Res* 5(3): 951-960; 1978.

Apurinic DNA endonuclease activity from cultured human fibroblasts was resolved into two species by phosphocellulose chromatography. The species had sedimentation coefficients of 3.38 and 2.88 and apparent Km's for apurinic sites of 5 and 44 nM, respectively. Cell lines from normal individuals, from a patient with ataxia telangiectasia, and from patients with the A and D complementation groups of xeroderma pigmentosum were compared. The low Km species was absent from extracts of the three cell lines of xeroderma pigmentosum complementation group D. The significance of this finding is not known. (21 refs)

78-4380 **Selective Particle Deposition and Bronchogenic Carcinoma.** (Eng) Schlesinger, R. B. (Inst. Environmental Medicine, New York Univ. Medical Center, 550 First Ave., New York, NY, 10016); Lippmann, M. *Environ Res* 15(3): 424-431; 1978.

Regional and intrabronchial particle deposition patterns determined in experimental inhalation tests using a hollow cast of the human tracheobronchial tree, γ-tagged aerosols, and a collimated radiation detector were compared to the distribution of sites of origin of primary bronchogenic tumors in the upper bronchial tree obtained from published reports. The test aerosols consisted of tagged (^{99}Tc) ferric oxide microspheres under three conditions of constant inspiratory-type flow (15, 30, and 60 liters/min). These flow rates correspond to the av flow rates reported for rest, light work and heavy work, respectively. Particles covering a similar size range as those used in this test make up a large part of the mass in urban atmospheric aerosols and their surfaces could act as vectors for transport of carcinogens into the respiratory tract. It was estimated, from published reports, that 10% of all bronchogenic carcinomas arise in the main bronchi, 30% in the lobar bronchi, 30% in the segmental bronchi, and 30% in bronchi distal to the segmental. Particle deposition was calculated to be lowest in the main bronchi and greatest in the lobar and segmental bronchi. This pattern was similar for the range of particle sizes and exposure flow rates tested. The deposition data suggest that bifurcations in the lobar and segmental bronchi receive higher doses than those at other branching levels, which may partly explain the higher cancer incidences at these sites. The deposition characteristics of the airways may play a significant role in cancer pathogenesis. (31 refs)

78-4381 **Use of Parabiont Mice to Study the Histogenesis of Sarcomas Induced by Plastic Plates.** (Rus) Moizhess, T. G. (Lab. Mechanisms Carcinogenesis, Cancer Res. Center, Moscow, USSR). *Tsitologiia* 20(2): 215-217; 1978.

To determine whether sarcomas induced by plastic plates originate from local connective tissue cells or from cells migrating with the blood, a 22- x 15-mm polyvinyl chloride plate was implanted sc in parabiotic pairs of 3-mo-old male CBA mice (each pair had a common abdominal cavity). One of the mice in each pair had a marker T_6 chromosome. Cytogenetic analysis of the developed tumors showed that the karyotype of all tumors corresponded to that of the host mouse. (8 refs)

78-4382 **Mortality from Leukaemia and Cancer in Shipyard Nuclear Workers.** (Eng) Najarian, T. (193 Lewis Road, Belmont, MA, 02178); Colton, T. *Lancet* 1(8072): 1018-1020; 1978.

A review of death certificates in New Hampshire, Maine, and lassachusetts for 1959-1977 yielded a total of 1,722 deaths mong former workers at the Portsmouth Naval Shipyard, here nuclear submarines are repaired and refueled. ontact with the next of kin was possible for 592 ien. All deaths under age 80 were classified as being n former nuclear or non-nuclear workers depending n information supplied by the next of kin. With US ge-specific proportional cancer mortality for white ien as a standard, the observed vs expected ratio f leukemia deaths was 5.62 (6 observed, 1.1 expect- d) among the 146 former nuclear workers. For all cancer eaths, this ratio was 1.78. Among non-nuclear workers, iere was no statistically significant increase in proportional iortality from either leukemia or from all cancers. The ex- ess proportional leukemia and cancer mortality among nu- lear workers exceeds predictions based on previous data of idiation effects in man. (4 refs)

8-4383 **Dielectric Characterization of UICC Asbestos Samples.** (Eng) Fleming, D. W. (Dept. Physics, aurentian Univ., Sudbury, Ontario, Canada); Rubin, G. A. *owder Technol* 20(2): 261-271; 1978.

n attempt was made to determine the mobility of charges n Union Internationale Contre le Cancer (UICC) samples f Canadian chrysotile and on South African amosite asbes- s. The former showed relatively large energy dissipation iaxima and they were slightly thixotropic at volume concen- ations as low as 0.5%. The latter were dielectrically inactive and they did not show thixotropic behavior up to fiber concentrations of 1.0 volume %. (15 refs.)

78-4384 **Elimination of Asbestosis (Letter to Editor).** (Eng) Matalani, E. (Occupational Health Unit, 509 Pitt St., Sydney, New South Wales 2000, Australia). *Med J Aust* 1(3): 157; 1978.

The use of Kaowool, a mineral ceramic fiber made from kaolin, as a substitute for asbestos is proposed. However, since a crystalline form of silica (Cristobalite) can be detected in the fused material when Kaowool is heated to high temperatures (1,250 C for 500 hr), its potential health hazards, ie, mesothelioma production, should be investigated. It is suggested that a threshold limit value of 10 mg/m^3 be used until testing is complete. (2 refs)

78-4385 **On Epizootiology of Lymphoid Leukosis in Chickens.** (Eng) De Boer, G. F. (Dept. Virology, Central Veterinary Inst., Houtribweg 39, Lelystad, Netherlands); Maas, H. J.; Van Vloten, J. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 19-24; 1978.

The prevalence of lymphoid leukosis (LL) virus infections and clinical disease was studied among laying-type chickens of an egg production testing station in the Netherlands during 1972-1976. The horizontal transmission of LL was also studied in 1-day-old and 8-wk-old chicks with high titers of maternal antibody to LL viruses. Viremia was detected in 31.6% of the 3- to 6-wk-old cockerels from the testing station, and homogenates of the spleen and bursa of Fabricius were positive in 40.8% of the birds tested. Viremia was present in 11.3% of the female hatch mates tested at 20 mo of age. Using WBC preparations, 21.9% of the 19-mo-old birds tested were virus-positive. The mean mortality due to LL was 0.43% during 1973-1974 and 2.8% and 1.28%, respectively, during the following 2 yr. Overt clinical disease occurred in 152/9,790 chickens under observation. The LL virus isolated belonged to subgroup A in 97% of the cases and to subgroup B in 3%. Antibody to subgroup A was rare in the 3- to 6-wk-old viremic birds, but it was found in 32% of the 20-mo-old viremic birds. In the horizontal transmission study, the plasma from 7-mo-old birds that had been exposed to LL-infected hatch mates at 1 day or 8 wk of age was virus-negative. However, a number of WBC preparations from the same birds were virus-positive. The data suggest LL virus can be transmitted horizontally and that chickens develop a resistance to LL virus infection with increasing age. (14 refs.)

78-4386 **Transformation Parameters in Chicken Fibroblasts Transformed by AEV and MC29 Avian Leukemia Viruses.** (Eng) Royer-Pokora, B. (Biologisch-Medizinische Abteilung, Max-Planck-Institut fur Virusforschung, Spemannstrasse 35, 7400 Tubingen, W. Germany); Beug, H.; Claviez, M.; Winkhardt, H. J.; Friis, R. R.; Graf, T. *Cell* 13(4): 751-760; 1978.

The expression of transformation parameters was studied in chicken fibroblasts (derived from clonal strains of chicken embryo fibroblasts) transformed by two model-defective leukemia viruses, avian erythroblastosis virus (AEV) strain ES4 and avian myelocytomatosis virus strain MC29. Fibroblasts transformed by Rous sarcoma virus (RSV) were analyzed for comparison. Infection with AEV or MC29 led to a rapid morphological transformation of most cells. AEV- and RSV-transformed fibroblasts were similar in that they exhibited microvilli at their surface, showed a disappearance of actin cables, were agglutinable by lectins, and showed a decrease in large, external, transformation-sensitive (LETS) protein (a high mol-wt cell-surface glycoprotein) and an increase in the rate of hexose uptake. They also had elicited slightly increased levels of cell-associated proteolytic activity, but no increase in the fibrinolytic activity of the harvested fluids. They were capable of anchorage-independent growth and of sarcoma induction. MC29-transformed fibroblasts also showed a disappearance of actin cables, and they were agglutinable by lectins, formed surface alterations that consisted of bleblike protrusions, and were capable of anchorage-independent growth. However, MC29-transformed fibroblasts expressed normal levels of LETS protein, had no increase in the rate of hexose uptake or in proteolytic activity, and were not sarcomagenic, although they showed an accelerated growth rate in culture. It is possible that MC29 and, perhaps, AEV transform fibroblasts by a mechanism different from that of RSV. (38 refs)

78-4387 **Normal Chicken Cells (chf-) Express a Surface Antigen Which Cross-reacts with Determinants of the Major Envelope Glycoprotein (gp85) of Avian Myeloblastosis Virus.** (Eng) Collins, J. J. (Dept. Surgery, Duke Univ. Medical Center, Durham, NC, 27710); Montelaro, R. C.; Denny, T. P.; Ishizaki, R.; Langlois, A. J.; Bolognesi, D. P. *Virology* 86(1): 205-216; 1978.

Attempts were made to distinguish chick helper factor-positive (chf+) cells from chf- cells using rabbit antisera raised against the purified major envelope glycoprotein (gp85) of avian myeloblastosis virus (AMV) in several serological assays, including competition radioimmunoassay and membrane immunofluorescence. However, chf+ cells coul not be differentiated from chf- cells. Radioimmunoprecipitation analysis of material recognized in uninfecte chf(+) and chf(-) chicken cells by the rabbit anti-AM gp85 antisera revealed the presence, in immune precipitates of both cell types, of a high-mol-wt glycoprotei (approx 125,000 daltons); however, low amounts o gp85 were precipitated only from the chf(+) cells. I contrast, antisera raised against the gp85's of Pragu strain Rous sarcoma virus (RSV: subgroup C), Bratislava-77 strain RSV (subgroup C), or Rous-associated virus type O did not recognize the 125,000-dalton molecule in either cell type, although gp85 was again precipitated from the chf(+) cells. The high-mol-wt glycoprotein, designated normal chicken glycoprotein, appears to represent a

ormal chicken cell-surface glycoprotein that is antigenically
ross-reactive with unique determinants of AMV gp85 that
e presumably dependent on the carbohydrate portion of the
olecules. (32 refs)

3-4388 **Anomalous Behavior of the Major Avian
Myeloblastosis Virus Glycoprotein in the Pres-
ıce of Sodium Dodecyl Sulfate.** (Eng) Marciani, D. J. (Lab.
umor Virus Genetics, NCI, Bethesda, MD, 20014); Papa-
atheakis, J. D. *J Virol* 26(3): 825-827; 1978.

he major glycoprotein of avian myeloblastosis virus (AMV)
as characterized using polyacrylamide gel electrophoresis
AGE) and gel filtration in the presence of sodium dodecyl-
ılfate (SDS). The apparent mol wt of the glycoprotein de-
eased from 140,000 with 4% acrylamide to a limiting value
81,000 with 10% acrylamide. The use of retardation coeffi-
ents yielded a mol wt for the AMV glycoprotein of 64,000.
Vhen gel chromatography in SDS was used to determine the
pparent mol wt of the glycoprotein from its hydrodynamic
operties alone, the estimated value was 50,000. It is con-
uded that the generally assigned value of 80,000 daltons for
e AMV major glycoprotein, as determined by SDS electro-
ıoresis, may be an overestimate because of its relatively low
ee electrophoretic mobility and peculiar confirmation in
DS. The true mol wt of the AMV glycoprotein must conse-
uently be determined by alternative methods such as sedi-
entation analysis in the presence of detergents or amino
id analysis in combination with specific chemical cleavage
the polypeptide chain. (13 refs.)

8-4389 **Quantitative Analysis of MC29 Virus in Plasma
of Hepatoma-Bearing Turkey Poults by Deter-
ination of Reverse Transcriptase Activity and Radioim-
uno-Assay.** (Eng) Talas, M. (Microbiological Res. Group
Hungarian Acad. Sciences, Budapest and D. I. Ivanovsky
ıst. Virology, Moscow, USSR); Zakharova, L. G.; Stoger,
; Altstein, A. D.; Piker, E. G. *Acta Microbiol Acad Sci Hung*
(4): 323-329; 1977.

nalysis of reverse transcriptase (RT) activity was compared
ith radioimmunoassay (RIA) of specific viral proteins for
e quantitative determination of myelocytomatosis virus 29
4C29) in MC29 hepatoma-bearing turkey poults.
ne-day-old turkey poults were infected iv with the virus,
ıd plasma was collected from tumor bearers on day 12
ostinfection. Pellets of virus particles obtained by
entrifugation were resuspended in buffer soln. Max
ral RT activity was obtained after incubation of
e reaction mixture containing the virus preparation
r 180 min at 20 C or for 120 min at 37 C. Opti-
um conditions also included the presence of
025%-0.2% Triton X-100 and 6 mM $MgCl_2$ or 0.5 mM $MnCl_2$ in the mixture. The best exogenous template for the reaction was poly(rA)-oligo(dT). A direct relation existed between plasma dilution and RT activity. A mixture of labeled p19 and p27 of avian myeloblastosis virus (AMV) was used as a standard in the RIA. The number of virions in the AMV pool used was known; therefore, the number of MC29 virions in the plasma preparations could be calculated. The data indicated that RIA was more sensitive than analysis of RT activity for the quantitative determination of MC29 virus. With RIA, virus could be detected even in 10^{-4} dilutions of plasma, but only two- to fourfold dilutions could be used with the RT analyses. (14 refs)

78-4390 **Isolation of Lymphoid Leukemia Virus in Hens.** (Rus) Popova, L. S. (No affiliation given); Zelensky, V. P.; Zaretskaya, L. I. *Veterinariia* (7): 99-100; 1977.

The assay for routine isolation of chicken leukemia virus is described. Initial virus-containing specimens were obtained from the internal organs of 1 to 10-day-old chicken with histologically confirmed diagnosis of leukemia or from 8 to 11-day-old embryos of virus-bearing chicken. Tissue specimens were centrifuged, filtered and cell-free filtrate was tested in reaction of complement fixation (RCF) for the presence of antigen GS. RCF-positive filtrates were incubated with chicken embryo fibroblast (CEF) monolayer cultures. The third generation of CEF was tested for immune fluorescence (RIF). Virus-containing cultures (RIF-positive) were then inoculated into 1 to 3-day-old chicken (0.2-0.3 ml, ip); the bio-test was considered positive, if chicken developed histologically verified leukemia, or if their sera contained group-specific or type-specific antigen. (no refs)

78-4391 **Tumor Antigen Induction by the Envelope-defective Bryan Strain of Rous Sarcoma Viruses.** (Eng) Kurth, R. (Friedrich-Miescher-Laboratorium, Max-Planck-Institut, 74 Tubingen, W. Germany); Kitchener, G. *J Natl Cancer Inst* 60(6): 1365-1369; 1978.

The expression of tumor-specific cell-surface antigen(s) (TSSA) was studied in chicken, quail, and turkey cells infected and/or transformed by wild-type avian leukosis and sarcoma viruses (ALV, ASV) or by the envelope-defective Bryan high-titer strain of Rous sarcoma virus [BH-RSV(-)]. All fibroblast-transforming ASV, including BH-RSV(-), were able to induce the expression of TSSA. Thus, TSSA was group-specific for all transforming ASV. Since BH-RSV(-) is a stable deletion mutant lacking the capacity to code for the 85,000-dalton major virus envelope glycoprotein (gp85), it is unlikely that TSSA is antigenically related to the gp85 of endogenous or exogenous ALV and ASV. (29 refs)

78-4394 **Correlation of Procollagen mRNA Levels in Normal and Transformed Chick Embryo Fibroblasts with Different Rates of Procollagen Synthesis.** (Eng) Rowe, D. W. (Dept. Pediatrics, Univ. Connecticut Health Center, Farmington, CT, 06032); Moen, R. C.; Davidson, J. M.; Byers, P. H.; Bornstein, P.; Palmiter, R. D. *Biochemistry* 17(9): 1581-1590; 1978.

Procollagen (PC) messenger RNA (mRNA) obtained from chick embryonic tendon cells, cultured fibroblasts, and fibroblasts transformed by Rous sarcoma virus (RSV) was measured by translation in a modified reticulocyte lysate and by hybridization with a complementary DNA (cDNA). The lysate was treated with Staphylococcal nuclease to destroy endogenous mRNA and chromatographed on a Sephadex column to reduce the endogenous amino acid content. The optimal conditions for PC mRNA translation included 40 mM sodium, 6 mM phosphate, and 0.4 mM spermidine in addition to the usual reagents. With these methods, PC mRNA activity could be detected in cells synthesizing only 1%-2% PC. The immunoprecipitable product was degraded by collagenase, and it migrated slightly slower than authentic secreted PC upon polyacrylamide gel electrophoresis. PC mRNA was isolated from embryonic chick tendons and purified by oligo(dT)-cellulose chromatography and sucrose gradient centrifugation. The mRNA activity was located in the 27S region of the gradient; this RNA was used to synthesize PC cDNA. The purified cDNA was about 900 nucleotides long, it was specific for PC mRNA, and it hybridized to 75% with RNA from cells synthesizing PC. The PC mRNA concentration correlated well with procollagen synthesis rates in tendon fibroblasts in situ, fibroblasts in culture, and in RSV-transformed fibroblasts. When tendon fibroblasts were grown in culture, the PC mRNA concentration fell about threefold; the concentration was 1.5-fold lower at high cell density than at low density. RSV transformation lowered PC mRNA levels another four- to tenfold at both high and low density. These results indicate that the extent of PC synthesis is determined primarily by PC mRNA levels rather than by translational control. (43 refs)

78-4395 **Concordance of the RNA Termini of Recombinants from Crosses Between Avian Retroviruse with Different Termini.** (Eng) Joho, R. H. (Institut fu Molekularbiologie I, Universitat Zurich, Honggerberg, 809 Zurich, Switzerland); Billeter, M. A.; Weissmann, C. *Virology* 85(2): 364-377; 1978.

The 5′- and 3′-terminal RNase T_1-resistant oligonucleotide of avian retroviruses and recombinants arising from crosse between them were analyzed. The parent viruses were (1 ts337-C, a temperature-sensitive mutant of the Prague C strain of Rous sarcoma virus (Pr RSV-C), and Rous-associated virus 6 (RAV 6) and (2) Prague B strain RSV and RAV 1. In a previous study, several RNA recombinants appeare to contain the 5′-proximal part of one parent and the 3 proximal part of the other parent; however, the termin regions themselves were not analyzed. Of the 10 recombinants examined in this study, all contained 5′- and 3′-termina regions derived from only one of the parents. The structure of the termini were compatible with the existence of subterminal redundancy in all recombinant viral RNA's, as has bee demonstrated for the parental RNA's of Pr RSV-C and avia myeloblastosis virus. Six of the 10 recombinants had crossovers in the immediate vicinity of the viral termini, possibly a a consequence of proviral DNA synthesis. (31 refs)

78-4396 **The Distribution of Virus-Specific RNA i Rous Sarcoma Virus-induced Hamster Tumo Cells.** (Eng) Brugge, J. S. (Dept. Pathology, Univ. Colorad Medical Center, Denver, CO, 80262); Purchio, A. F.; Erikson, R. L. *Virology* 83(1): 27-33; 1977.

The size distribution of virus-specific RNA in the nucleus an cytoplasm of Rous sarcoma virus (RSV)-transformed hamster cells was studied. Cytoplasmic RNA from cloned cell derived from tumors induced in Syrian hamsters by th Schmidt-Ruppin strain of RSV was fractionated int polyadenylated and nonpolyadenylated RNA. The nonpolyadenylated RNA contained no detectable viral RNA sequences. When the polyadenylated RNA was fractionated b sucrose density gradient centrifugation and the RNA fron each fraction hybridized with ^{3}H-complementa DNA (^{3}H-cDNA), only one peak of viral RNA w detected. This species sedimented at the same rate the 21S class of virus-specific RNA found in RS infected chicken cells, and there was no change i size pattern in late-passage tumor cells that becam negative for group-specific antigens. Hybridizatio of fractionated nuclear RNA with ^{3}H-cDNA produce three classes of virus-specific nuclear RNA sedimenting a 47S, 35S, and 21S. Sedimentation of nuclear RNA unde denaturing conditions did not change this size distribution The data suggest that the nonpermissive behavior o RSV-transformed cells is related to improper processing o viral RNA in the cells. (19 refs)

3-4397 A Mutant of Rous Sarcoma Virus with a Thermolabile Defect in the Virus Envelope. (Eng)
ato, F. (Instituto Superiore di Sanita, 00161 Rome, Italy);
eamand, J. A.; Wyke, J. A. *Virology* 88(1): 71-81; 1978.

he temperature sensitive (*ts*) defect in *LA*30A, a mutant of
ie Prague strain of Rous sarcoma virus (RSV), was studied.
eplication of the mutant was studied by the formation of
ifective centers. The heat-labile virion component of *LA*30A
fected the initiation of transformation and replication, in-
icating that the lesion was of the early coordinate type. The
efective component of *LA*30A appeared to function before
rovirus synthesis, in that the time required for it to pass
ırough its *ts* stage was far shorter than for *LA*335, which
as a *ts* RNA-dependent DNA polymerase. Also, once *LA*
0A penetrated the cell, the infection was no longer *ts*.
seudotypes of both Bryan high-titer strain RSV and vesicu-
ır stomatitis virus with envelopes donated by *LA*30A
howed heat lability typical of the mutant. All these data
trongly suggest that *LA*30A possesses a *ts* defect in the viral
nvelope glycoproteins. When the mutant underwent pheno-
ypic mixing with Rous-associated viruses (RAV), the *ts* de-
ect was stabilized, even when the infected cells lacked recep-
ors for RAV envelope glycoproteins. The possible reasons
or this effect are discussed. (29 refs.)

**8-4398 Aggregation of Platelets and Cell Membrane Vesiculation by Rat Cells Transformed In Vitro
y Rous Sarcoma Virus.** (Eng) Gasic, G. J. (Dept. Pathology,
Jniv. Pennsylvania, Sch. Medicine, Philadelphia, PA,
9104); Boettiger, D.; Catalfamo, J. L.; Gasic, T. B.; Stewart,
3. J. *Cancer Res* 38(9): 2950-2955; 1978.

The acquisition of in vitro platelet-aggregating activity was
nvestigated in normal rat kidney cells transformed by the
377 strain of Rous sarcoma virus (RSV), and LR primary
at embryo cells transformed by the Schmidt-Ruppin strain
f RSV. Both types of transformed cells induced the aggrega-
ion of rat platelets in vitro. The aggregating activity was
pecific for the transformed cells and was absent in the nor-
nal parent cells. The aggregation reaction was accompanied
y the release of serotonin from the platelets. Further study
ınd purification of this activity from the transformed cells
lemonstrated that the activity was shed from the cells grow-
ng in culture and that it was associated with membrane vesi-
les of heterogeneous size. Normal cells also produced vesi-
les in culture, but the level of vesicle production was less
han that in the transformed cells. Furthermore, the platelet
ggregation and serotonin release activities in these vesicles
vere greatly reduced or absent. (32 refs.)

**78-4399 Selection of Nonidentified Viral Sequences of the Avian Sarcoma and B77-C Virus (Meeting
Abstract).** (Fre) Pluquet, N. (Unite de Virologie, U. 102 INSERM, place de Verdun, 59045 Lille Cedex, France); Stehelin, D. *Bull Cancer (Paris)* 65(1): 40; 1978. (no refs)

78-4400 Resistance to Marek's Disease. Effect of *Corynebacterium parvum* and Marek's Tumor Cell Vaccines on Tumorigenesis in Chickens. (Eng) Donahoe, J. (Dept. Veterinary Preventive Medicine, Ohio State Univ., 1900 Coffey Road, Columbus, OH, 43210); Kleven, S.; Eidson, C. *J Natl Cancer Inst* 60(4): 829-833; 1978.

Tumor formation was studied in chickens after nonspecific cell-mediated immunity (CMI) stimulation with *Corynebacterium parvum* and specific CMI stimulation with fixed Marek's disease (MD) tumor cells. Nonspecifically stimulated outbred White Leghorn-type cockerels had higher incidences of tumors than did controls. A study of tumor cell cytotoxicity of sera from MD virus-exposed birds indicated that humoral factors may have some role in MD tumor cell control, but probably not a major one. The results suggest that cellular immunity is more important in MD tumor cell vaccine protection than humoral immunity. (21 refs)

78-4401 Sites of Integration of Reticuloendotheliosis Virus DNA in Chicken DNA. (Eng) Keshet, E. (McArdle Lab. Cancer Res., Univ. Wisconsin, Madison, WI, 53706); Temin, H. M. *Proc Natl Acad Sci USA* 75(7): 3372-3376; 1978.

The pattern of integration of spleen necrosis virus (SNV) DNA in DNA from a large population of SNV-infected chicken cells was studied by nucleic acid hybridization with iodinated viral RNA with the use of a blotting technique. SNV DNA was found to be integrated at multiple sites in acutely infected chicken cells. Concomitantly with the transition from acute to chronic infection, pattern of integration shifted. The majority of integrated SNV DNA found in acutely infected cells was absent from chronically infected cells. This result is consistent with the hypothesis that the cell death that occurs after infection of avian cells with reticuloendotheliosis viruses is a consequence of the multiple integrations of the provirus. Viral DNA was also integrated at multiple sites in chronically infected cells. However, infectious viral DNA molecules in chronically infected cells migrated uniformly during agarose gel electrophoresis after *Eco*RI digestion (which does not cut viral DNA), indicating that not all integrated SNV copies are equally infectious. (20 refs.)

78-4402 Biochemical Evidence of the Nonintegrated Status of Marek's Disease Virus DNA in Virus-Transformed Lymphoblastoid Cells of Chicken. (Eng) Tanaka, A. (Lab. Molecular Virology, Life Sciences, Inc., St.

Petersburg, FL, 33710); Silver, S.; Nonoyama, M. *Virology* 88(1): 19-24; 1978.

The status of latent virus genomes in MKT-1 cells, a lymphoblastoid cell line derived from a kidney tumor in a Marek's disease virus (MDV)-infected chicken, was studied. The cells were virus-nonproductive, and they contained 15 copies of MDV genomes per cell, 80%-90% of which was separable from the high-mol-wt cellular DNA. The fast-sedimenting viral DNA from MKT-1 cells showed values of 90S to 100S in a neutral glycerol gradient and a value of 200S in an alkaline glycerol gradient, indicating that the 100S DNA is probably in the form of closed circular molecules. When 100S molecules were centrifuged to equilibrium in an ethidium bromide-CsCl gradient, at least 60% of the molecules were located in the region where the simian virus 40 DNA component 1 was found. It is possible that the circular plasmid form of viral DNA is the stable and preferred form in herpesvirus-transformed cells. (16 refs.)

78-4403 **Herpesviruses and Cancer (Letter to Editor).** (Eng) Makari, J. G. (Makari Res. Labs., Inc., Englewood, NJ, 07631). *Lancet* 1(8076): 1256-1257; 1978.

An association between Marek's disease herpesvirus (MDHV) and human cancer, including carcinoma of the colon, is reported. An immunological technique capable of detecting 0.1 femtogram, a sensitivity more than a million times that of radioimmunoassay methods, was used. The association was based on the finding of common antigenicity between glycoprotein antigens extracted from human cancers and those extracted from tumors of chickens infected with MDHV. Additional evidence for this association is given. (4 refs)

78-4404 **Transformation of Indian Muntjac Cells by Murine and Avian Sarcoma Viruses.** (Eng) Yuasa, Y. (Inst. Medical Science, Univ. Tokyo, Shiroganedai 4-6-1, Minato-ku, Tokyo 108, Japan); Hirai, R.; Huh, N. H.; Shimojo, H.; Yamamoto, T. *Gann* 69(3): 441-445; 1978.

The transformation of Mm-2K Indian muntjac cells by murine sarcoma virus (MSV) and avian sarcoma virus (ASV) is reported. Of the various MSV and ASV strains tested, only the MSV with the envelope properties of xenotropic murine leukemia virus (X-MuLV) [MSV(X-MuLV)], the B77 strain of ASV subgroup C, and the Schmidt-Ruppin strain of Rous sarcoma virus subgroup D (SR-RSV-D) were capable of transforming the cells. Colony formation in soft agar was examined by infecting monolayers of Mm-2K cells with high multiplicities of infection of the transforming viruses. After 2 wk, many colonies were seen in the SR-RSV-D-infected cells and a few were noted in the B77-infected cells, but no colonies were seen in the MSV(X-MuLV)-infected cells. The ASV-transformed cell clones differed from each other w respect to morphology, presence of inducible ASV genor and karyotype. (8 refs.)

78-4405 **The Effect of Heat-inactivated Muri Cytomegalovirus on Host DNA Synthesis Different Cells.** (Eng) Gonczol, E. (Dept. Microbiolo Medical Sch. Debrecen, 4012 Debrecen, Hungary); Stone, Melero, J. M. *J Gen Virol* 39(3): 415-426; 1978.

Heat-inactivated murine cytomegalovirus (MCMV) stimul ed cellular DNA synthesis in whole mouse embryo cells, n mal murine mammary gland cells, murine fibrobla (BALB/c 3T3 A31), Chinese hamster fibroblasts (WgI primary chicken embryo cells, and Syrian hamster fibrobla (NIL-8), as evidenced by a two- to eightfold increase in incorporation of methyl-^{3}H-thymidine into the total DNA virus-infected cells. Incorporation of label was lower or changed with active or UV-treated MCMV. NIL-8 and ch cells were the least susceptible to virus replication and w thus chosen for further experiments. During the 48-hr stu period, both nuclear and mitochondrial DNA (nDNA a mDNA) synthesis was stimulated in these cells, but there no viral DNA synthesis. The stimulation of nDNA synthe was about 5 times greater in NIL-8 nDNA and about times greater in chick cell nDNA than in mock infected ce as measured by rate of incorporation of ^{3}H-thymidine. T stimulation was about 9.5-fold in NIL-8 and 1.7-fold in ch cells as detected by autoradiography. There was a 3-fold a 2.2-fold increase in the incorporation of label into the mDN of NIL-8 and chick cells, respectively. The amount of mDN in both kinds of infected cells was about twice that in cont cells. The synthesis of mDNA was also stimulated by a fac of 2 in thymidine kinaseless 3T3 cells that incorporate exo nous thymidine exclusively into mDNA. Although MCMV specific antigens were detectable by immunofluor cence at 5 hr after infection, diffuse nuclear antigens w demonstrated in NIL-8 and chick cells 24 hr after infecti Since there was no virus DNA synthesis in the cells, th antigens can be considered early antigens, coded for by parental virus DNA. (29 refs)

78-4406 **Immunohistochemical Detection of Cross-reacting Virus Antigen in Mouse Ma mary Tumors and Human Breast Carcinomas.** (E Mesa-Tejada, R. (Inst. Cancer Res., Coll. Physicians Surgeons Columbia Univ., 701 W. 168th St., New York, N 10032); Keydar, I.; Ramanarayanan, M.; Ohno, T.; Fenog C.; Speigelman, S. *J Histochem Cytochem* 26(7): 532-5 1978.

An indirect immunoperoxidase method was used to local mouse mammary tumor virus (MMTV) antigens in para sections of mammary tumors of Paris RIII and CD8F$_1$ m nd to detect an antigen that cross-reacts with a group-specif- antigen (gp52, a 52,000-dalton glycoprotein) of MMTV in araffin sections of human breast carcinomas. The specificity f the staining reaction with antibody against MMTV was xamined by absorption of IgG with: (1) purified gp52; (2) everal relevant and irrelevant viral preparations; (3) normal uman plasma, WBC breast tissue, milk, actin, collagen, and yaluronic acid; (4) sheep RBC, bovine mucin, and fetal calf erum. Only MMTV and purified gp52 eliminated the im-nunohistochemical reaction in human breast tumors. Posi-ive reactions were seen in 73/191 human breast carcinomas f various histopathologic types, but negative reactions were btained in all 137 normal and benign cases tested. A positive eaction of uncertain specificity was observed in foci of apo-rine metaplasia. With one exception, 99 carcinomas from 13 rgans other than breast and 8 cystosarcomas were negative. 40 refs.)

8-4407 **Polyproteins Related to the Major Core Protein of Mouse Mammary Tumor Virus.** (Eng) Dick-on, C. (Imperial Cancer Res. Fund Labs., Lincoln's Inn Fields, London, WC2A 3FX, England); Atterwill, M. *J Virol* 26(3): 660-672; 1978.

Immunoprecipitation with monospecific antiserum and tryptic peptide analysis were used to characterize the polyproteins related to the major core protein, p27, of murine mammary tumor virus (MuMTV). Immunoprecipitation of cell extracts derived from the mammary tumor cell lines GR and Mm5MT with anti-MuMTV-p27 serum resulted in the isolation of several proteins with mol wts of 34,000 to 160,000. Pulse-chase experiments and tryptic peptide analyses of these proteins demonstrated that p77/75, p61, p48, p38, and p34 were related by amino acid sequence to p27 of the virion. The p34 to p61 proteins were probably derived by proteolytic cleavage of the p77/75 protein. After a 15-min pulse with ^{35}S-methionine, all of the p27-related proteins in the GR and Mm5MT cell lines were labeled and, during a subsequent chase, all progressively disappeared. The p27 was labeled poorly during the pulse, but the amount of label increased during the chase. The majority of the p27-related proteins were rapidly turned over in the cell rather than being processed into p27. The GR and Mm5MT cell lines showed a clear difference in their ability to convert the presumptive precursors into p27. When MuMTV was isolated from the culture medium of mammary tumor cells harvested at 5-min intervals, the major p27-related protein was p34. p27 accounted for only 29% of the anti-p27 serum immunoprecipitable proteins, compared with 95% in virus isolated from an 18-hr harvest. Incubation of the rapid-harvest virus at 37 C for 2 hr resulted in some conversion of p34 to p27. The data suggest that some of the p27 in MuMTV is formed in the virions by proteolytic cleavage of p34. (41 refs.)

78-4408 **Bioactivity of Male (Sperm Transmitted) Mouse Mammary Tumor Virus as Influenced by Donor, Recipient and Age at Treatment.** (Eng) Squartini, F. (Spedali Riuniti di S. Chiara, Istiuto di Anatomia e Istologia Patologica, Via Roma 57, 56100 Pisa, Italy); Di Coscio, G. *Tumori* 64(2): 103-114; 1978.

Sperm collected from mammary tumor virus (MTV)-carrying mice (C3H, BALB/cfC3H, BALB/cfRIII, and RIII) was tested separately for its mammary tumor-inducing activity in (BALB/c x C3Hf)F_1, (BALB/c x RIIIf)F_1, and BALB/c female recipients inoculated ip with 0.1 ml of the sperm at age 1-2 wk or 3 mo. A total of 551 recipients were observed, including control mice. Mammary tumor incidence was not affected by the presence or absence of histocompatibility between the sperm donors and the recipient mice. The incidence was related to the type of sperm-transmitted MTV (C3H or RIII), and it was influenced by age at inoculation. MTV of C3H origin tended to be more effective than that of RIII origin in 1- to 2-wk-old recipients, whereas the latter was equally effective in both age groups. BALB/c recipients were susceptible to C3H infection, but (BALB/c x RIIIf)F_1 hybrids were resistant to sperm-released MTV, especially to C3H infection. These hybrids had a 34% incidence of late spontaneous lymphomas inherited by the RIIIf male parent. (BALB/c x C3Hf)F_1 hybrids were susceptible to both C3H and RIII sperm-released MTV, and they had a 30% incidence of late spontaneous mammary tumors due to genetic transmission of MTV by the C3Hf male parent. (40 refs.)

78-4411 **Biological and Biochemical Differences Among Ecotropic C-Type RNA Viral Isolates Chemically Induced from C57BL/Ka Mouse Embryo Cells in Vitro.** (Eng) Gelmann, E. P. (Cancer Biology Res. Lab., Dept. Radiology, Stanford Univ. Sch. Medicine, Stanford, CA, 94305); Decleve, A.; Kaplan, H. S. *Virology* 85(1): 198-210; 1978.

The role of selection pressure on the characteristics of endogenous ecotropic viruses isolated from C57BL/Ka mouse embryo fibroblasts was studied, and the isolates were compared with those from radiation-induced lymphomas arising in this strain. Selection pressure has been found to operate during the isolation of viruses after in vitro induction by 5′-iododeoxyuridine (IUdR). During passage in cultures of both Fv-1 genotypes, it became apparent that the IUdR-induced viral isolates differed distinctively with respect to their Fv-1 tropism and XC plaque-forming ability. These differences appeared to depend on the type of overlay cell in which each virus was first recovered after induction, its subsequent intracellular passage history, its extracellular transfer from one culture to another, and the purification of particles by endpoint dilution on permissive cell lines. Although the original induced isolates were N-tropic, B-tropic virus emerged during passage of one of the isolates. Two distinct N-tropic viruses were also recovered in the process, one of which appears to be identical to BL/Ka(N). Polyacrylamide gel electrophoresis was also used to compare the polypeptides of the viral isolates. Differences in the electrophoretic behavior of the low-mol wt polypeptides were observed that seem to correlate with specific types of viruses classified on the basis of biologic criteria. Similar selection pressures applied to murine RNA virus isolates by in vivo and in vitro manipulations probably explain the numerous discrepancies in the literature with respect to their biologic activities. (39 refs)

78-4412 **Differential Activation of Endogenous Murine Retrovirus in Mouse-Monkey Somatic Hybrids (Meeting Abstract).** (Fre) Sergiescu, D. (INSERM U5, Hopital Cochin, Paris, France); Rousset, S.; Gisselbrecht, S.; Sinoussi, F. *Bull Cancer (Paris)* 65(1): 35; 1978. (no refs)

78-4414 **Cellular Immune Response Induced by the Radiation Leukemia Virus (RadLV).** (Eng) Peled, A. (Dept. Chemical Immunology, Weizmann Inst. Science, Rehovot, Israel). *Leuk Res* 1(4): 333-343; 1977.

The dynamics of the appearance of the cell-mediated immunity responsible for leukemic cell destruction were investigated in female C57BL/6 mice inoculated intrathymically with 0.02 ml of radiation leukemia virus (RadLV). This immunization made the mice resistant to the isotransplantation of leukemic cells (5 x 10^5) for 2 mo. Lymphoid cells from the thymus, lymph nodes, spleen, and peritoneal exudate of immune mice retarded tumor growth. RadLV-inoculated mice had transplantation resistance only to leukemic cells induced by RadLV (127 LC), but not to radiation-induced leukemias
(XRL-1, XRL-2, XRL-3), to EL_4, or to any other syngene
tumors tested. The immunological specificity of the lympho
cells from immunized mice was tested in vivo and in vit
against C57BL/6 leukemic cells induced by RadLV, chem
cal carcinogens, and x-rays. The cells were found to be high
specific for the presence of RadLV associated antigens c
their cell surface. A cytostatic effect rather than a cytolyt
effect was noted when effector:leukemic cell interaction w
tested in vitro. (38 refs)

78-4415 **Cytolysis and Transformation Induced**
Leukemogenic Recombinant Radiation Le
kemia Virus Isolated from Thymoma Cell Lines and by Vir
from Leukemic Thymus Epithelial-Reticulum Cells. (En
Haas, M. (Dept. Cell Biology, Weizmann Inst. Scienc
Rehovot, Israel). *In: Advances in Comparative Leukemia R*
search 1977. Proceedings of the VIIIth International Sympo
um on Comparative Research on Leukemia and Related D
ease, held in Amsterdam, The Netherlands on 22-
August, 1977. Bentvelzen, P.; Hilgers, J.; Yohn, D.
eds. (New York Elsevier/North Holland Biomedi
Press): 503 pp.; 115-126; 1978.

Various properties of the thymotropic leukemogenic vir
produced by the 136.5 thymoma cell line and of virus pr
duced by growth on leukemic thymus epithelial reticulu
cell monolayers are presented. Virus produced by bo
sources was found to be cytolytic and replication defecti
Some of the viruses were able to induce foci in, and morph
logically transform, mink lung cells. The thymotrop
leukemogenic virus was also shown to be recombinant in t
major surface glycoprotein gp70, which contains informati
from both ecotropic and xenotropic viruses. As a model f
this recombination, it is suggested that (1) during ecotrop
proviral integration, the ecotropic virus recombines with re
dent xenotropic viral sequences; (2) the infected thymus e
thelial reticulum cells can thus synthesize recombinant vir
in addition to ecotropic virus; and (3) infection of susceptib
thymocytes or thymocyte precursor cells occurs
cell-to-cell contact. It is conceivable that only a minority
the recombinant viruses synthesized would be able to infe
and transform thymocytes. Those that transform thymocyt
will be amplified and found frequently, but the others w
be rare. (26 refs)

78-4416 **Transmission of Autoimmune Haemolytic An**
mia and Murine Leukaemia Virus to Hybr
Progeny of Allophenic NZB <—> CFW and NZB <
BALB/c Male Mice. (Eng) East, J. (Dept. Immu
pathology, Imperial Cancer Res. Fund, Burtonh
Lane, Mill Hill, London NW7 1AD, England); Harv
J. J.; Tuffrey, M.; Tilly, R. J. *Clin Exp Immunol* 31(
260-269; 1978.

illy, R. J. *Clin Exp Immunol* 31(2): 260-269; 1978.

he transmission of autoimmune hemolytic anemia and mu-
ine leukemia virus (MuLV) was studied in 116 progeny of
llophenic (tetraparental) NZB<->CFW and NZB<->
ALB/c male mice. Of two NZB<->CFW males mated to
ormal albino BALB/c partners, one had an NZB (black)
nd the other a CFW (white) genotype, producing agouti-col-
red F_1(BALB/c x NZB) and albino F_1(BALB/c x CFW)
rogeny, respectively. The former developed a protracted
ourse of autoimmune hemolytic disease and diverse lym-
hoid, lung, and liver tumors and carried C-type MuLV.
ith respect to these features, they were identical to F_1
BALB/c x NZB) natural hybrids. On the other hand, no
utoimmune hemolytic anemia, very little virus, and a pre-
onderance of lung tumors developed in the albinos. A third
ZB<->BALB/c male also sired agouti F_1 and varicolored
$_2$(BALB/c x NZB) hybrids showing the same pattern of
utoimmunity, malignancies, and virus infection. When this
nale was additionally mated to NZB females, he produced
wo generations of black (NZB x NZB) descendants that dis-
layed the typical NZB profile of autoimmune hemolytic dis-
ase. Therefore, only the progeny of allophenic fathers having
he NZB genotypes expressed autoimmunity and large num-
ers of MuLV particles. It is concluded that both autoim-
nunity and virus were transmitted by incorporation of genet-
c information. The range and type of malignancies were also
genetically determined. These findings suggest that the sole
virus in NZB mice is xenotropic. (11 refs)

78-4417 **Assignment of the Receptor for Ecotropic Murine Leukemia Virus to Mouse Chromosome 5.** (Eng) Ruddle, N. H. (Dept. Epidemiology, Yale Univ., New Haven, CT, 06520); Conta, B. S.; Leinwand, L.; Kozak, C.; Ruddle, F.; Besmer, P.; Baltimore, D. *J Exp Med* 148(2): 451-465; 1978.

The genetic control of ecotropic (mouse-tropic) murine leukemia virus (MuLV) replication was analyzed at the receptor level. The experimental material consisted of clones derived from crosses between Chinese hamster cells (E36, a line that segregates murine chromosomes) and murine peritoneal exudate cells (A/HeJ and *Mus poschiavinus* strain I) or embryo fibroblasts (BALB/c). Mouse-Chinese hamster hybrids were analyzed for susceptibility to ecotropic MuLV infection by the vesicular stomatitis virus (MuLV)[VSV(MuLV)] pseudotype assay and the XC cell assay. Segregation of mouse chromosomes in the hybrids was analyzed by chromosome banding and isozyme expression. The ability of the hybrid cells to absorb and replicate both VSV(MuLV) pseudotype virus and ecotropic MuLV segregated with chromosome 5 was demonstrated. Three statistical procedures confirmed that chromosome 5 was essential for receptor expression. Segregation of the receptor in two series of subclones demonstrated that, in both, receptor expression was syntenic with phosphoglucomutase-1, an isozyme that has been mapped to mouse chromosome 5. On the basis of these results, the gene for the receptor for ecotropic MuLV (*Rev*) has been assigned to mouse chromosome 5. (35 refs.)

78-4418 **Are Bone Marrow Derived Fibroblastoid Colony-Forming Cells Involved in Viral Leukemogenesis?** (Eng) Zipori, D. (Radiobiological Inst. TNO, Lange Kleiweg 151, Rijswijk, Netherlands). *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 314-315; 1978.

Bone-marrow derived fibroblastoid colony-forming cells were studied in mouse strains with a low and high incidence of spontaneous leukemia. A correlation was noted between high leukemia incidence and ecotropic virus-producing fibroblastoid cells in the marrow. If these cells are involved in regulating hemopoiesis, their infection by leukemia viruses could be the cause of preleukemic hemopoietic changes. They could also be the site of malignant transformations of hemopoietic cells by simultaneously providing differentiation signals and oncogenic viruses. (2 refs)

78-4419 **Detection of Vesicular Stomatitis Virus (Murine Leukemia Virus) Pseudotypes by Immunoelectron Microscopy.** (Eng) Chan, J. C. (Dept. Molecular Carcinogenesis and Virology, Univ. Texas System Cancer Center, M. D. Anderson Hosp. Tumor Inst., Houston, TX, 77030); Hixson, D. C.; Bowen, J. M. *Virology* 88(1): 171-176; 1978.

Immunoelectron microscopy (IEM) was used to detect vesicular stomatitis virus (VSV) pseudotypes formed by superinfection of a murine leukemia virus (MuLV)-producing rat bone tumor cell culture with the temperature-labile VSV mutant t1-17. The VSV pseudotype was detected by IEM as bullet-shaped VSV particles reacting with anti-MuLV serum. The IEM observation of VSV(MuLV) pseudotype formation was confirmed by the results of thermostability and neutralization tests. It is expected that IEM will find broader application for the demonstration of other pseudotypes that cannot be assayed readily by conventional infectivity assays. (14 refs.)

78-4420 **Immunocytochemical Detection of a Murine Leukemia Virus-related Nuclear Antigen in Mouse Oocytes and Early Embryos.** (Eng) Piko, L. (Developmental Biology Lab., Veterans Admin. Hosp., Sepulveda, CA 91343). *Cell* 12(3): 697-707; 1977.

The expression of murine leukemia virus (MuLV)-related antigens in oocytes and early embryos of Swiss mice was studied using the unlabeled antibody peroxidase-antiperoxidase method with antiserum to the major core protein (30) of AKR MuLV. At antibody dilutions up to 1:500, intense staining of the germinal vesicles of oocytes and the interphase nuclei of early embryos was noted. Nuclear staining was restricted to a specific period of oocyte growth and development. It developed gradually in oocytes having reached one-third to one-half the full-grown size, and it persisted until meiotic maturation. In early embryos, nuclear staining was present from the one-cell stage to the morula, but it disappeared after transition to the blastocyst. Nuclear staining was abolished by absorption of anti-p30 serum with disrupted virions of Gross(A), AKR, Kirsten and Moloney MuLV, and Kirsten murine sarcoma virus, but not with the Friend and Rauscher strains of MuLV, xenotropic BALB:virus 2, a mouse-tropic and an amphotropic clone of wild mouse MuLV, or with feline leukemia virus and Rous sarcoma virus. Anti-p30 serum reacted with an AKR MuLV preparation to produce a strong band in the p30 region upon electrophoresis; smaller strongly reacting bands with approx mol wts of 65,000 and 38,000 daltons were also detected. These findings demonstrate the development of stage-dependent expression of MuLV p30-related antigen in mouse oocytes and early embryos. (63 refs.)

78-4421 **Analysis of Erythroid Precursor Cells in Friend Virus Infected Mice.** (Eng) Bertoncello, I. (Dept. Clinical Physiology, Univ. Ulm, 7900 Ulm, Germany); Opitz, U.; Seidel, H. J. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 285-287; 1977.

In DBA/2 mice infected with polycythemia-inducing strain of Friend virus (FV-P), the normal population of colony-forming units - erythropoietic (CFU-E) was replaced by an erythropoietin (EP)-independent CFU-E population, and the numbers of burst-forming units - erythropoietic (BFU-E) became undetectable. Normal and EP-independent CFU-E did not differ in modal sedimentation velocity. However, following velocity sedimentation of FV-P-infected marrow cell suspensions, BFU-E reappeared at a modal sedimentation velocity not significantly different from that of controls, which precludes the theory that their disappearance is a result of stem cell damage. 78-4423 **A Single Non-H-2 Gene is Required f**
H-2b/b-Associated Recovery from Friend Vi
Leukemia in Mice. (Eng) Chesebro, B. (Rocky Mount
Lab., NIH, Hamilton, MT); Wehrly, K. *In: Advances*
Comparative Leukemia Research 1977. Proceedings of
VIIIth International Symposium on Comparative Research
Leukemia and Related Diseases, held in Amsterdam, T
Netherlands on 22-26 August, 1977. Bentvelzen, P.; Hilge
J.; Yohn, D. S., eds. (New York: Elsevier/North Holla
Biomedical Press): 503 pp.; 69-73; 1978.

The backcross murine population (C57BL/10 x A.BY)F
A.BY, in which genes other than the major histocompatib
ty complex (H-2) were segregating, was studied to determi
the number of C57BL genes involved in the recovery fr
H-2b/b-associated Friend virus (FV) leukemia. When A.
mice (H-2b/b) were inoculated with B-tropic FV (FV-
75% developed marked leukemic splenomegaly within
days and none showed any indication of recovery from l
kemia. In contrast, the (C57BL/10 x A.BY)F_1 mice (a
H-2b/b) showed a high incidence of recovery (79% at
days), although splenomegaly was evident in 72% by day
Within 68 days after inoculation,45%(C57BL/10 x A.BY)
x A.BY backcross mice had recovered from leukemia, s
gesting that a single, autosomal, dominant, non-
C57BL/10 gene is required for expression of
H-2b/b-associated effect on recovery from FV leuken
When recombinant-inbred C x B (BALB/c x C57BL
mouse strains were tested for recovery from FV leukemia,
difference in FV-2 genotypes between the (C x B) E a
(C57BL/10 x BALB/B)F_1 mice did not appear to influe
recovery from FV leukemia. Although the identity and m
location of the non-H-2 C57BL/10 gene necessary for rec
ery in the A.BY backcross population are not known,
latter experiments indicate that the FV-2 gene is not lik
to be required. (10 refs.)

rine Virus-Infected Erythroleukemia Ce
(Eng) Tanaka, M. (Dept. Human Genetics and Developme
Sch. Physicians and Surgeons, Columbia Univ., New Yo
NY). *Tohoku J Exp Med* 124(1): 13-20; 1978.

The effects of dimethyl sulfoxide (DMSO) on the synth
of chromosomal proteins in murine virus-infected e
throleukemia cells (MELC) were studied. DS 19 cells clo
from MELC line 745A were incubated with 280 mM DM
The cells showed a reduced rate of growth during the f
48 hr, but the number of cells approximated that in cont
MELC cultures by 96 hr. The number of benzidine-react
cells increased progressively up to 91.0% at 5 days; cont

ultures contained only 0.2% benzidine-reactive cells at 5 ays. The rate of total protein synthesis was much lower in he DMSO-treated cells than in control cells: at 96 hr, the ates were 8.33 and 13.00 cpm x 10^{-5}, respectively. The synhesis of histone increased twofold in the 48-hr-incubation DMSO-treated cells, but that of nonhistone protein was not timulated. Histone synthesis was max at 48 hr, and by 72 r it had declined. ^{3}H-Leucine-labeled DMSO-treated cells were mixed with ^{14}C-labeled control cells and the ^{3}H/^{14}C atios in the histone fractions were monitored. At 48 hr, there was a 3.6-fold increase in the ratio in fraction 3 and 3.4-fold ncrease in fraction 2b. The data indicate that the stimulation f histone synthesis is an early event following DMSO treatment of MELC. (13 refs.)

8-4425 **Proteins of Transcriptionally Active and Inactive Chromatin from Friend Erythroleukemia Cells.** (Eng) Lau, A. F. (Dept. Microbiology, Univ. Minnesota, Minneapolis, MN, 55455); Ruddon, R. W. *Exp Cell Res* 107(1): 35-46; 1977.

Transcriptionally active and inactive chromatin fractions were prepared from control and dimethyl sulfoxide (DMSO)-treated murine erythroleukemia cells by a DNase II digestion technique. The active and inactive chromatin fractions from control and DMSO-treated cells had essentialy the same total histone content, but the active chromatin fractions from both control and treated cells contained significantly less H1 histone. The amount of nonhistone protein was similar in the corresponding chromatin fractions of control and DMSO-treated cells. For both treated and control cell chromatin, however, the content of nonhistone protein was consistently lower in the inactive fraction than in the active fraction. No significant differences were observed between the polyacrylamide gel banding patterns (determined by Coomassie blue staining) of histone or nonhistone chromatin proteins of the corresponding fractions from treated and control cells. However, dual-radioisotope-labeling studies indicated an increased incorporation of radioactive amino acids into a 50,000-dalton polypeptide of unfractionated chromatin and a 23,000-dalton polypeptide of active chromatin from DMSO-treated cells. The significance of the elevated incorporation of labeled amino acids into the 50,000- and 23,000-dalton polypeptides is not currently evident. (41 refs)

78-4426 **Comparison of RNA Components from Feline and Rodent Sarcoma-Leukemia Virus Complexes.** (Eng) Kimball, P. C. (Ohio State Univ. Comprehensive Cancer Center, Columbus, OH, 43210). *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 235-236; 1978.

The S values of RNA subunits from two feline and two murine sarcoma-leukemia virus isolates (FeSV-FeLV, MuSV-MuLV) were compared in an attempt to determine the source(s) of feline oncornavirus genetic information. MuSV-MuLV isolates had a 38S MuLV component, with uniform S values in all MuLV isolates, and a more slowly moving MuSV subunit with varying S values in different isolates. FeSV-FeLV complexes contained two or three distinct RNA subunits with different S values, all lower than those for the MuLV RNA subunits. The most slowly sedimenting (25S) RNA subunit from all feline viruses was observed only in preparations containing FeSV, suggesting that this RNA component is FeSV-specific. It was also found in virus stocks obtained by rescue of FeSV with FeLV from nonproducer cells transformed with FeSV in the absence of helper virus. Electrophoresis of various RNA components suggested that the 30S-40S RNA subunits of all self-replicating C-type viruses examined (MuLV's, FeLV of different serotypes, and RD114 endogenous cat virus) have a mol wt of approx 2.3 x 10^6 daltons, despite sedimentation data suggesting mol wt differences of $> 5\%$. In contrast, the defective Rickard FeLV RNA, which lacks methylated caps on the 5′ end, and two different strains of FeSV-FeLV had mol wts of about 2.1 x 10^6 daltons. This finding suggested that specific degradation of FeLV RNA near the 5′ end is a frequent occurrence. (no refs)

78-4427 **Nucleotide Sequence Homology of Mammalian RNA Tumor Viruses.** (Eng) East, J. L. (Dept. Molecular Carcinogenesis and Virology, Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., Houston, TX, 77030); Nell, L. J.; Knesek, J. E.; Chan, J. C.; Dmochowski, L. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 141-143; 1978.

A competition hybridization assay was used to quantitate nucleotide sequence relationships of C-type mammalian RNA tumor viruses. Representive members of three viral groups were examined: Friend leukemia virus, Gross leukemia virus, Moloney sarcoma virus, Kirsten leukemia virus (MuLV-K), and Kirsten sarcoma virus (MSV-K) of the murine group; gibbon ape leukemia virus and simian sarcoma virus of the simian group; and RD-114 virus of the feline group. Reciprocal cross-hybridization data revealed that (1) the murine viruses can be placed into four unrelated subgroups, with MuLV-K and MSV-K belonging to the same subgroup; (2) the two simian viruses belong to different yet related subgroups; and (3) RD-114 virus does not share sequence homology with any other virus examined. (5 refs)

78-4428 **Identification of an FMR Cell Surface Antigen Associated with Murine Leukemia Virus-infected Cells.** (Eng) Nowinski, R. C. (Fred Hutchinson Cancer Res. Center, Seattle, WA, 98104); Emery, S.; Ledbetter, J. *J Virol* 26(3): 805-812; 1978.

FMR-specific viral and cell-surface antigens, which are found on the surface of cells infected with exogenous murine leukemia viruses [MuLV: Friend (F), Moloney (M), and Rauscher (R)] were analyzed immunochemically. A variety of antisera were prepared in mice, and their reactivity against the FMR antigens of Friend, Moloney, and Rauscher MuLV was determined. In absorption tests, the cytotoxic activity of FMR antisera was removed by disrupted density gradient-purified FMR MuLV and by FMR MuLV-infected cells, but not by purified endogenous MuLV or by cells infected with endogenous viruses. Antisera prepared against G antigens (found on the surface of cells infected with endogenous or Gross MuLV) were cytotoxic for unlabeled target cells. The cytotoxic reaction of the G typing antiserum was absorbed by unlabeled target cells, but not by normal mouse spleen cells and only partially by MuLV leukemia cells. In absorption tests with viruses of the FMR and G serotypes, FMR antisera reacted primarily with the gp70, p15(E), and p12(E) proteins of MuLV. Reactions with the p15(E) and p12(E) proteins were based exclusively on the detection of group-specific antigens, whereas the reactions with gp70 were based on the detection of type-specific and group-specific antigens. G antiserum detected antigenic determinants of the major core protein, p30, of endogenous MuLV. The results of cytotoxic absorption tests and immune precipitation assays with extracts of radiolabeled cells indicated that cells infected with endogenous MuLV contained the viral envelope protein gp70 and the glycosylated polyprotein precursors of the internal structural proteins of MuLV on their cell surfaces. FMR antisera reacted with the gp70 proteins of these cells, but not with the glycosylated core polyproteins. In contrast, the G antiserum reacted with both gp70 and the glycosylated proteins. It is concluded that FMR cell-surface antigen is a determinant on the MuLV *env* gene product. (24 refs.)

78-4429 **Surface Expression of Murine Leukemia Virus Structural Polypeptides on Host Cells and the Virion.** (Eng) Schneider, J. (Forschergruppe Tumorimmunologie, D-7800 Freiburg, W. Germany); Hunsmann, G. *Int J Cancer* 22(2): 204-213; 1978.

The expression of murine leukemia virus structural polypeptides on the surface of cells producing exogenous Friend leukemia virus, endogenous ecotropic AKR virus, and xenotropic BALB/c virus was investigated. Antisera to Friend virus gp71, p30, p15E, p12, and p10 were employed in a complement-dependent chromium release assay and in the immunoprecipitation of lactoperoxidase iodinated surface polypeptides prior to their analysis by polyacrylamide gel electrophoresis. With the latter technique, gag gene-encoded proteins and their precursors were not discovered on the virus- and cell-surface membranes. Only the env gene-enco ed polypeptides gp85, gp71 and p15E were detectable. p15 was embedded into the lipid membrane, and gp85 was forme by disulfide linkage of p15E to surface-exposed gp71. Tl ratio of gp71 to gp85 was variable and apparently determine by the host cell. Antibodies of strong cytotoxicity were tho against type- and group-specific epitopes of gp71 as well type-specific epitopes of p12. (40 refs.)

78-4430 **Hormone-Sensitivity Profiles of Virus-induce T-Lymphocyte Malignancies (Meeting A stract).** (Eng) Peterson, R. D. (Dept. Pediatrics and Pha macology, Univ. South Alabama Coll. Medicine, Mobil AL, 36617); Funkhouser, J. D.; Palmer, G. C. *Fed Proc* 37(6 1748; 1978. (no refs)

78-4431 **Isolation of a Cell-Surface Antigen Associate with Gross Virus in Liposomes.** (Fre) Gerlie D. (Laboratoire d'Immunologie, Centre Leon-Berard, 28, ru Laennec, 69373 Lyon Cedex 2, France); Sakai, F.; Dore, F. *C R Acad Sci [D] (Paris)* 286(5): 439-442; 1978.

A Gross virus-associated cell-surface antigen was extracte from (C58NT)D lymphoma cells by detergent solubilizatio of the membranes and then partially purified. Absorption ex periments, in which the cytotoxicity of W/Fu r anti-(C58NT)D serum toward E(male)G_2 lymphoma cel was determined, indicated that the antigen was located on th surface of sensitized liposomes. (13 refs)

78-4432 **Glycoproteins from Murine C-Type Virus a more Acidic in Virus Derived from Transforme Cells than from Nontransformed Cells.** (Eng) Forchhamme J. (Fibiger Lab., 2100 Copenhagen, Denmark); Turnock, C *Virology* 88(1): 177-182; 1978.

Viral proteins from purified Moloney-murine sarcoma viru (murine leukemia virus) [M-MSV(MuLV)] and M-MuL grown in established BALB/3T3 cells in vitro were studie using two-dimensional electrophoresis. Several of the vir proteins were present in multiple forms differing in charg but not in size, and, except for the glycoprotein gp70, th isomers were identical in virus from transformed (TF) an nontransformed (NTF) cells. The gp70 from both types virus showed 10 to 15 spots, indicating great charg heterogeneity. The gp70 from virus from TF cells had isoele tric points that were an av of 1 pH unit more acidic than th gp70 from NTF cells, and their apparent mol wt was in creased slightly. That the TF state of the culture was impo tant for these differences to occur was substantiated using mutant M-MSV(MuLV) that is temperature-sensitive fo maintenance of transformation. It is likely that the viral gp7 is one of the substrates for the increased activity of sialyltransferase found in transformed cells. (23 refs.)

78-4433 **Genome Organization of RNA Tumor Viruses. II. Physical Maps of In Vitro-synthesized Moloney Murine Leukemia Virus Double-stranded DNA by Restriction Endonucleases.** (Eng) Verma, I. M. (Tumor Virology Lab., Salk Inst., San Diego, CA, 92112); McKennett, M. A. *J Virol* 26(3): 630-645; 1978.

In vitro-synthesized double-stranded DNA from Moloney murine leukemia virus (M-MuLV) was cleaved with the restriction endonucleases (RE) *Sal* I, *Hind* III, *Bam* I, *Hpa* I, *Sma* I, and *Bgl* I + II in an effort to construct physical maps of the M-MuLV genome. *Sal* I and *Hind* III cleaved the viral DNA at only one site generating two fragments each. The fragments generated by *Sal* I, designated *Sal* IA and *Sal* IB, had mol wts of 3.5 x 10^6 and 2.4 x 10^6, respectively. The *Hind* III fragments had mol wts of 3.6 x 10^6 (*Hind* IIIA) and 2.3 x 10^6 (*Hind* IIIB). *Bam*I generated four fragments of mol wts 2.1 x 10^6 (*Bam* IA), 2 x 10^6 (*Bam* IB), 1.25 x 10^6 (*Bam* IC), and 0.21 x 10^6 (*Bam* ID). *Hpa* I generated three fragments of mol wts 4.4 x 10^6 (*Hpa* IA), 0.84 x 10^6 (*Hpa* IB), and 0.74 x 10^6 (*Hpa* IC). *Sma* I generated four fragments of mol wts 3.9 x 10^6 (*Sma* IA), 1.3 x 10^6 (*Sma* IB), 0.28 x 10^6 (*Sma* IC), and 0.21 x 10^6 (*Sma* ID). A mixture of *Bgl* I and *Bgl* II generated five fragments of mol wts 2 x 10^6 (*Bgl* I + IIB), 1.25 x 10^6 (*Bgl* I + IIC), 0.40 x 10^6 (*Bgl* I + IID), and 0.31 x 10^6 (*Bgl* I + IIE). The order of the fragments in relation to the 5′ and 3′ ends of the genome was determined for each enzyme separately by using fractional-length M-MuLV double-stranded DNA for digestion by the RE or by redigestion of the *Sal* IA, *Sal* IB, *Hind* IIIA, and *Hind* IIIB fragments with other RE. Other RE that cleaved in vitro-synthesized M-MuLV double-stranded DNA were *Ava* I, *Sst* I, *Xho* I, *Xba* I, *Bgl* I, *Bgl* II, *Hind* II, *Hae* II, *Hpa* II, *Hin* f, and *Hae* III. (22 refs.)

78-4434 **Nonproducer Malignant Tumor Cells with Rescuable Sarcoma Virus Genome Isolated from a Recurrent Moloney Sarcoma.** (Eng) Weiland, E. (Federal Res. Inst. Animal Virus Diseases, Tubingen, W. Germany); Mussgay, M.; Weiland, F. *J Exp Med* 148(2): 408-423; 1978.

The viral, oncogenic, and antigenic properties of a transplantable tumor that reappeared at the site of a primary regressed Moloney sarcoma were studied to obtain information on the escape of tumor cells from immune destruction. Cells from the recurrent tumor were passaged in STU mice by im and ip inoculation. Tumors induced by these cells and a cell line derived from them grew progressively and led to the death of the animal 3-7 wk after transplantation. There was no evidence of virus production or of viral antigens in the tumor cells. Infection with helper virus allowed rescue of the sarcoma virus genome and led to the establishment of a cell line producing focus- and XC plaque-forming virus. The nonproducer cells were not immunogenic, but the producer cells possessed a strong immunogenicity. However, tumors induced by the producer cells frequently grew progressively. Although, they were nonimmunogenic, the nonproducer cells showed weak immunosensitivity when used as challenge cells in the transplantation protection assay or as target cells for the demonstration of antibody-mediated cytotoxicity and cell-mediated cytotoxicity, if the immune response was induced by cells producing the sarcoma-helper virus complex, but not by cells producing only helper virus. It was assumed that the recurrence of the regressed Moloney sarcoma was the result of transformed nonproducer cells escaping immune destruction and not of a depleted immune resistance in the host. (31 refs.)

78-4435 **Biochemical Characterization of the Amphotropic Group of Murine Leukemia Viruses.** (Eng) Chattopadhyay, S. K. (Pediatric Oncology Branch, Div. Cancer Treatment, NCI, Bethesda, MD, 20014); Hartley, J. W.; Lander, M. R.; Kramer, B. S.; Rowe, W. P. *J Virol* 26(1): 29-39; 1978.

Amphotropic murine leukemia virus (MuLV) strain 1504-A, isolated from feral mice (*Mus musculus*) in the La Puente trapping area of California, was studied by nucleic acid hybridization to determine its relationship to other MuLV's and to determine the distribution of the genome sequences in various mouse strains. A $[^3H]$DNA probe synthesized in an endogenous reaction from detergent-lysed 1504-A indicated that the amphotropic MuLV's are distinct biochemically: 20% of the viral genome sequences were not shared by AKR-type ecotropic or any of the three types of xenotropic MuLV's (NZB-IU-1, BALB-IU-1, and Cas E No. 1-x) tested. One-half of these amphotropic unique sequences were present in the genome of wild mouse ecotropic viruses and in Moloney and Rauscher viruses. Sequences homologous to the entire genome of 1504-A amphotropic virus were present in the cellular DNA of all eight inbred mouse strains tested, as well as in wild *Mus* in Asia, in amounts varying from three to six complete viral genomes per haploid cell genome. At least 20% of the DNA sequences in both mouse- and mink-grown MuLV probes were found to be of host cell origin. (34 refs)

78-4436 **Genetic Control of Sensitivity to Moloney-Virus-induced Leukemias in Mice. I. Demonstration of Multigenic Control.** (Eng) Gisselbrecht, S. (Laboratoire d'Immunologie et Virologie des Tumeurs-U.152, Hopital Cochin, Batiment G. Roussy, 27 rue du Faubourg-Saint-Jacques, 75674 Paris Cedex 14, France); Pozo, F.; Debre, P.; Hurot, M. A.; Lacombe, M. J.; Levy, J. P. *Int J Cancer* 21(5): 626-634; 1978.

The appearance of hematopoietic malignancies and viremia levels were studied in Moloney leukemia virus (MLV)-infected mice of nine inbred strains and their F_1 or F_2 hybrids. The mice were inoculated ip at age 3-4 wk with 0.1 ml of MLV at a 1:300 dilution, and they were surveyed for viremia at 3 wk and 2, 4, and 6 mo postinoculation by radioimmunoassay of the major internal virion component p30. The level of circulating virus was controlled by at least two genes, of which a histocompatibility (H-2)-linked gene (tentatively designated *Rmv-1*) displayed a dominant sensitivity. Alleles for resistance existed in the H-2b and H-2r haplotypes and alleles for sensitivity in H-2a, H-2d, and H-2f. Another gene with dominant resistance mapped outside the H-2 complex and probably interacted with *Rmv-1*. Although there was a good correlation between viremia and the appearance of leukemia, genes that were not involved in viremia control could be determinants in leukemia induction. One with a resistant allele in DBA-2 mice inhibited leukemia development despite high viremia levels. Another gene controlled the spleen involvement that results in generalized leukemias in sensitive lines, as opposed to the thymus-localized tumors in resistant animals. (38 refs)

78-4437 **Homology Between Cellular Repeated Nucleotide Sequences and a Murine Leukemia Viral Genome.** (Eng) Ginelli, E. (Istituto di Biologia Generale, Facolta di Medicina, Universita degli Studi, Via Viotti 5, 20133 Milan, Italy); Gianni, A. M.; Corneo, G. *Tumori* 64(4): 383-388; 1978.

Moloney murine leukemia virus complementary DNA was hybridized to an excess of NIH-Swiss mouse spleen DNA that had been fragmented to different lengths, heat-denatured, renatured (Cot = 50), and fractionated on an Ag^+/Cs_2SO_4 gradient according to extent of renaturation. The results confirm that the genome of an RNA oncogenic virus contains nucleotide sequences homologous to cellular repeated sequences. (12 refs)

78-4438 **Alterations in Chromatin of Cells Infected with RNA Tumor Viruses.** (Eng) Schincariol, A. L. (Cancer Res. Unit, Univ. Western Ontario, London, Ontario N6A 5B7, Canada); Maher, P.; Rip, J. *Nucleic Acids Res* 5(7): 2617-2627; 1978.

Differences in the chromatin (Chr) between normal and virus-transformed cell lines and among different virus-infected cell lines were determined. These lines were a cloned line of lymphocyte-like TB cells, derived from a culture of fetal thymus and bone marrow from CFW/D mice; producer clone 124, derived after successive infection of TB cells with the Moloney complex of murine leukemia/sarcoma virus [MuLV(MuSV)]; producer clone 349; nonproducer clone 605; and nontransformed producer clone TB+MuLV (produces MuLV, but not MuSV). Chr's were isolated from infected TB cells and compared immunologically and bic
chemically. Chr from virus-infected cells did not fi
complement as well as Chr from uninfected cells, suggestin
that conformational changes had occurred in the forme
This alteration was detected within 24 hr of infection. Th
structural changes in the Chr appeared to reflect alteratior
in the nonhistone proteins as the quantity and mol wt of th
histone proteins did not vary. The nonhistone proteins wer
synthesized in greater amounts in the infected cells, especiall
four proteins of mol wt 52,000, 60,000, 70,000, and 80,00
The 60,000-dalton protein is of interest, as cells infected wit
RNA tumor viruses synthesize a similarly sized polycistron
protein precursor containing viral structural polypeptides.
is not known whether this protein is related to the viral pr
cursor or whether it is involved in regulating gene transcri
tion. The conformational changes in Chr occurred not onl
in cells transformed and producing virus (clones 124 an
349), but also in clones 605 and TB+MuLV. The chang
are presumed due to the specific transcription of viral RN
and possible alterations in the transcription of cellular gene
(29 refs.)

78-4439 **The Discovery of a Murine Sarcoma Viru
Transforming and Nondefective for Replicatio**
(Meeting Abstract). (Fre) Sinoussi, F. (Unite d'Oncolog
Virale, Institut Pasteur, 25, rue du Dr Roux, 750
Paris, France); Chermann, J. C. *Bull Cancer (Par*
65(1): 35; 1978. (no refs)

78-4440 **Arrangement of Murine Leukemia Provira
Genes Integrated in Chromatin.** (Eng) Panet, A
(Dept. Virology, Hebrew Univ.-Hadassah Medical Sch
Jerusalem, Israel); Cedar, H. *In: Advances in Comparativ
Leukemia Research 1977. Proceedings of the VIIIth Interna
tional Symposium on Comparative Research on Leukemia an
Related Diseases held in Amsterdam, The Netherlands c
22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn D. S
eds. (New York: Elsevier/North Holland Biomedical Press
503 pp.; 446-447; 1978.

The expression of murine leukemia proviral DNA genes wa
studied at the chromatin level by measuring the sensitivit
of these genes to DNase I. Isolated nuclei of Swiss NI
mouse cells infected with Moloney murine leukemia viru
(MuLV) were treated with DNase. The results indicated tha
at least 80% of the proviral sequences in these cells wer
clustered in regions of chromatin sensitive to nuclease dige
tion. The localization of endogenous proviral sequences wa
also studied in the uninfected parental cells. A random distr
bution of the proviral sequences between DNase I-sensitiv
and -resistant portions of the nuclear DNA was noted. Sinc
the Moloney MuLV-infected cells contained as much endog
nous DNA as the uninfected cells, it is concluded that bot
exogenous and endogenous proviral genes are susceptible t

Nase I in these cells. This suggests that the presence of ogenous virus affects the arrangement of chromosome pro-ins along endogenous viral genes. Examination of the corre-tion between proviral gene activity, virus production, and ie disposition of proteins along the integrated proviral se-uences suggested that during the cell cycle, there is a rear-ngement of the chromosomal proteins along the integrated roviral genes and that these proteins are involved in the egulation of proviral gene expression. (no refs)

8-4441 **Genetic Control of Immune Responses to Moloney Leukemia Virus in Rats.** (Eng) Jones, J. 1. (Dept. Pathology, Natl. Center Toxicological Res., Jeffer-on, AR, 72079); Jensen, F.; Feldman, J. D. *J Natl Cancer nst* 60(6): 1467-1472; 1978.

he nature of the genetic differences that control responses o antigens of Moloney murine leukemia virus (M-MuLV) nd their relationship to the major histocompatibility (*AgB*) ocus were investigated in BN and LEW rats. The rats were mmunized with untreated or formalin-inactivated M-MuLV, and their sera were examined by radioimmunoas-ay for antibody to p15, p30, and gp70. BN rats produced igh antibody responses to the viral antigens, whereas LEW ats were low responders. BN rats also exhibited a high re-ponse and LEW rats a low response when the two strains vere immunized with purified p30. Studies of (LEW x BN)F$_1$ and backcross rats suggested that factors as-ociated with *AgB* exerted major influences on res-ponses to antigens of M-MuLV and that other factors vere also important. When other rat strains (F344, DA, ACI, AUG, and BUF) representing five *AgB* alleles vere tested, some were high and some were low res-ponders to M-MuLV, and responses to p15, p30, and gp70 were not always parallel. Since M-MuLV replica-ion was greater in cells of BN rats than in cells of LEW rats, replication of M-MuLV may have influenced the levels of responses to some viral antigens. Control of virus replication appeared to be due to cell mechanisms rather than to the environment of the host. (34 refs)

78-4442 **Effect of Rauscher Leukemia Virus-specific Proteins on Reverse Transcriptase: Binding Between Reverse Transcriptase and p30.** (Eng) Bandyopadhyay, A. K. (Section Immunology and Cell Biology, Lab. Molecular Biology, NIH, NCI, Baltimore Cancer Res. Center, Baltimore, MD 21211). *J Biol Chem* 252(16): 5883-5887; 1977.

The reverse transcriptase (RT) from Rauscher leukemia virus (R-LV) was purified to homogeneity. The RT, a single polypeptide chain of 70,000 mol wt, interacted with the major internal protein p30 of R-LV. The RT p30 complex stimulated the incorporation of ^{3}H-thymidine monophosphate into oligodeoxythimidylic acid·polyriboadenylic acid two to threefold compared to RT alone. Monospecific antisera directed against either p30 or RT precipitated the entire complex. The RT·p30 complex had a mol wt of approx 400,000 by chromatography on Sepharose 6B and a sedimentation rate of 12S in a glycerol gradient. (32 refs)

78-4443 **Detection of Membrane-bound Type-C Viral Antigens on Murine Spleen Cells by an Antibody-dependent Cell-mediated Cytotoxicity Assay.** (Eng) Becker, M. J. (Clinical Immunology and Arthritis Section, Veterans Admin. Hosp., 4150 Clement St., San Francisco, CA, 94121); Blackman, M.; Talal, N. *Ann Immunol (Paris)* 129(2/3): 179-181; 1978.

The utility of antibody-dependent cell-mediated cytotoxicity (ADCC) as a detection system for membrane-bound C-type viral antigens on murine lymphocytes and lymphatic tumor cells was studied. ADCC activity against NZB/NZW mouse lymphoma 141 was mediated by rabbit antisera to Rauscher leukemia virus proteins (gp69/71 or p30) and human lymphoid effector cells. At a 10^{-2} dilution of anti-gp69/71, 66.3% to 11.3% of the 141 cells were killed at effector to target cell ratios of 50:1 and 2:1, respectively. Significant lysis was demonstrated at a 10^{-4} dilution of antiserum and an effector to target cell ratio of 10:1. The specific lysis of lymphoma 141 and NZB/NZW and CBA/J splenic lymphocytes coated with rabbit anti-Rauscher gp69/71 was also assessed. At an effector to target ratio of 10:1, both lymphoma 141 and NZB/NZW lymphocytes were lysed to an equal extent. CBA/J lymphocytes were lysed to a significanty lower degree at all antiserum dilutions tested. Under similar conditions, rabbit anti-Rauscher p30 was also able to induce lysis of lymphoma 141 and NZB/NZW spleen cells, but not CBA/J spleen cells. It is concluded that ADCC is a specific and reproducible method for detecting C-type viral proteins on the surface of live normal and malignant murine lymphocytes. (24 refs)

78-4447 **The Influence of Rauscher Leukemia Virus on the Hemapoietic System of BALB/c and DBA Mice. The Establishment of a New Erythroid Cell Line.** (Eng) de Both, N. J. (Dept. Experimental Pathology, Faculty Medicine, Erasmus Univ., Rotterdam, Netherlands); Vermey, M.; Klootwijk, E.; van't Hull, E.; Montfoort, A.; van Griensven, L. J.; Stoof, T. J. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 288-290; 1978.

Five days after BALB/c mice are infected with Rauscher murine leukemia virus (R-MuLV), islands of large immature blast cells arise and proliferate in the red pulp of the spleen with a doubling time of 7.5 days. About 96% of these cells are lost from the spleen, mostly through cell death. Studies indicated that erythropoiesis took place in the spleen and that the disease-associated progressive anemia appeared to be caused by a defect in peripheral RBC function. No permanent transformed lines could be obtained from BALB/c spleens, but one was established from R-MuLV-infected DBA mice. (8 refs)

A. (Univ. Wisconsin, Madison, WI, 53706); Duke, R. E.; Watson, A.; Bach, F. H. *Fed Proc* 37(6): 1570; 1978. (no refs)

78-4449 **Morphological Studies of Oncornaviruslike Particles from Human Haematological Malignancies.** (Eng) Mooren, H. (Lab. Pathology, State Univ. Leiden, Wassenaarseweg 62, 2300 RC Leiden, Netherlands); Warnaar, S.; Prins, F. *In: Advances in Comparative Leukemi Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Relate Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D.S., eds. (Ne York: Elsevier/North Holland Biomedical Press): 503 pp 154-155; 1978.

Viruslike particles were detected by electron microscopy i three tumors from patients with hematological malignanci (non-Hodgkin's lymphoma, myelofibrosis, and hairy ce leukemia). Computer analyses of the rotational symmetri of the particles showed that they had the same levels of tw and threefold symmetries as murine mammary tumor viru type B, and Rauscher murine leukemia virus, type C. The results strengthened the biochemical evidence (reverse tra scriptase and 70S RNA) for the presence of oncornavirus in the three tumors. (4 refs)

78-4450 **The Effect of Pseudotype on Abelso Virus-induced Leukemia.** (Eng) Scher, C. (Sidney Farber Cancer Inst., Harvard Medical Sch., Bosto MA, 02115); Stone, M. *In: Advances in Comparati Leukemia Research 1977. Proceedings of the VIII International Symposium on Comparative Research Leukemia and Related Diseases, held in Amsterdam, T Netherlands on 22-26 August, 1977.* Bentvelzen, Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/Nor Holland Biomedical Press): 503 pp.; 318-319; 197

Nonproducer Abelson murine leukemia virus (A-MuLV) w infected with NB-tropic Moloney MuLV, NB-tropic Rausc er MuLV, NB-tropic Friend MuLV, or N-tropic endogeno helper virus to prepare pseudotypes of A-MuLV. The help virus profoundly influenced the frequency of A-MuLV-i duced leukemia in vivo (Fv-1-nn CD-1 Swiss mice) and t frequency of C57/L mouse bone marrow cell transformati in vitro. This effect is not controlled by the murine Fv locus. The pseudotype of A-MuLV, rather than the presen of an added effective helper, controls transformation freque cy. (3 refs)

78-4451 **Purification and Characterization of DN Polymerases from the Plasmacytoma MOP 104E and Abelson Murine Leukemia Viruses.** (Eng) W mann, B. J. (Basel Institut fur Immunologie, Grenzache strasse 487, Postfach, CH-4005 Basel, Switzerland); Schmi J.; Takacs, B. *Eur J Biochem* 85(2): 571-579; 1978.

RNA-dependent DNA polymerases were isolated from t intracisternal A particles of plasmacytoma MOPC 104E a from Abelson murine leukemia viruses and characterize Both polymerases were similar in their elution patterns fro phospho- and diethylaminoethyl-cellulose, template speci cities, requirements for optimum activity, and inactivation by anti-(reverse transcriptase) antiserum. Both polymerases were associated with ribonuclease H activity. For mol wt determinations, antibody-precipitated enzymes were bound to staphylococcal-protein A-Sepharose, solubilized, and run on dodecyl sulfate/polyacrylamide gels. Their apparent mol wt was estimated to be 80,000. (35 refs)

78-4455 **Isolation of a Leukaemogenic Type-C Oncovirus from a Leukaemic Child.** (Eng) Nooter, K. (Radiobiological Inst. TNO, Lange Kleiweg 151, Rijswijk, Netherlands); Overdevest, J.; Dubbes, R.; Koch, G.; Bentvelzen, P.; Coolen, J.; Zurcher, C.; Calafat, J. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 471-474; 1978.

A C-type viral isolate from a leukemic child was characterized. Bone marrow cells from the child were cocultivated with A7573 canine cells. In early passages, C-type oncoviruses were released. Cocultivation of the infected canine cells with nonproducing K-NRK rat cells transformed by Kirsten murine sarcoma virus (MSV) produced a new MSV phenotype that could transform rabbit SIRC cells. A cell line (SKA21-3) derived from the transformed SIRC cells became a high virus producer. The virus proteins were closely related to those of simian sarcoma virus. Injection of SKA21-3 cells producing human helper virus pseudotypes of MSV plus human helper virus into rats induced sarcomas, erythroleukemias, and lymphosarcomas. When the MSV genome was eliminated from SKA21-3 virus, the resulting human-derived virus induced generalized lymphosarcomas in rats. The leukemogenicity of this virus in animals is suggestive of an etiological role for the virus in human disease. (11 refs)

78-4456 **Origin and Biological Properties of a New BALB/c Mouse Sarcoma Virus.** (Eng) Aaronson, S. A. (Lab. RNA Tumor Viruses, NCI, Bethesda, MD, 20014); Barbacid, M. *J Virol* 27(2): 366-373; 1978.

A focus-forming virus previously isolated from a BALB/c mouse hemangiosarcoma has been shown to be replication defective. Analysis of individual BALB/c mouse sarcoma virus (BALB-MSV) nonproducer transformants for expression of helper virus-coded proteins revealed genetically stable variants that expressed 2, 3, or all 4 *gag* gene products in the absence of detectable helper viral *env* gene expression. The type-specific antigenic determinants of helper viral proteins encoded by the BALB-MSV genome and by the B-tropic virus isolated from the BALB-MSV stock were demonstrated to be indistinguishable from those of BALB:virus-1, a known endogenous virus of BALB/c cells. These findings imply that a BALB/c endogenous virus was involved in the generation of BALB-MSV. By the same immunological approach, the presence of at least a portion of the Moloney murine leukemia virus *gag* gene has been identified in two other transforming viruses--Moloney-MSV and Abelson lymphosarcoma virus---previously isolated from the BALB/c strain. The tissue culture properties of cells transformed by these defective viruses were also shown to be distinguishable. These findings indicate that transforming virus isolates of the same inbred strain differ in their transforming activities as well as in the helper viral sequences stably associated with their genomes. (36 refs.)

78-4457 **Activation of Endogenous Type C Virus by Amino Acid Alcohols.** (Eng) Long, C. W. (Viral Oncology Program, Frederick Cancer Res. Center, Frederick, MD, 21501); Suk, W. A.; Greenawalt, C. *Virology* 88(1): 194-196; 1978.

Amino acid alcohols were examined for their ability to inhibit protein synthesis and induce endogenous C-type virus from Kirsten sarcoma virus (KiSV)-transformed Balb/c (K-Balb) mouse cells. Histidinol and tyrosinol proved to be highly effective short-term virus activators; valinol and methioninol gave low but reproducible activation. Histidinol, tyrosinol, and valinol were the most effective inhibitors of protein synthesis in this cell system, each reducing ^{3}H-leucine incorporation by > 95%. Methioninol reduced incorporation by 80%, and the other alcohols produced marginal effects. Treatment of K-Balb cells with amino acid alcohols did not induce virus capable of forming foci on Balb/c or NIH swiss monolayers. Decay of virus expression following induction with either histidinol or tyrosinol was rapid, and 24 hr after removal of histidinol, ^{3}H-leucine incorporation had returned to normal levels. Histidinol- or tyrosinol-induced virus activation was completely inhibited by actinomycin D or cytosine arabinoside, showing a requirement for RNA and DNA synthesis during induction. The fact that valinol efficiently blocks protein synthesis without appreciable virus activation indicates that a secondary process may be necessary for induction other than inhibition of protein synthesis. (10 refs.)

78-4458 **3T3 Variants Lacking Receptors for Epidermal Growth Factor Are Susceptible to Transformation by Kirsten Sarcoma Virus.** (Eng) Pruss, R. M. (Dept. Biological Chemistry, UCLA Sch. Medicine, Los Angeles, CA, 90024); Herschman, H. R.; Klement, V. *Nature* 274(5668): 272-274; 1978.

The susceptibility of variant Swiss 3T3 cells lacking receptors for epidermal growth factor (EGF) to transformation by Kirsten sarcoma virus was studied. The Swiss 3T3 parental cell line and three variants, NR1, NR4, and NR6, were essentially equivalent targets for transformation by Kirsten sarcoma virus, as determined by the number of foci produced. Assays for nuclear EGF receptors in preparations of membrane fragments from NR6 cells showed no membrane-associated EGF receptors; these receptors were demonstrated on parental 3T3 cells. Another assay for inactive substances that might block surface EGF receptors or bind to and/or degrade externally provided EGF showed no such inhibitory activity in extracts of either parental 3T3 or NR6 cells. The strictest interpretation of the data suggests that stimulation of mitogenesis by the action of a sarcoma gene product on EGF receptors is not the basis for uncontrolled growth as a consequence of transformation by murine sarcoma viruses. (7 refs)

78-4459 **FBJ Osteosarcoma Virus in Tissue Culture. III. Isolation and Characterization of Non-Virus-producing FBJ-transformed Cells.** (Eng) Levy, J. A. (Cancer Res. Inst., Univ. California, San Francisco, CA, 94143); Kazan, P. L.; Reilly, C. A.; Finkel, M. P. *J Virol* 26(1): 11-15; 1978.

The establishment and characterization of hamster and rat lines that have been transformed by FBJ murine sarcoma virus (FBJ-MuSV) but that do not produce virus are reported. The hamster line originated from an osteosarcoma that appeared in a Syrian hamster inoculated at birth with an extract of a CF 1 mouse FBJ osteosarcoma. The rat cell line was obtained by transferring the FBJ-MuSV genome to nor-
mal rat kidney cells in the absence of FBJ C-type virus (FB
murine leukemia virus), which usually accompanies FB
MuSV in high concentration. Both transformed hamster an
rat cell lines contained the FBJ-MuSV genome, and th
genome could be rescued by ecotropic and xenotropic murir
C-type viruses. The rescued genome produced characterist
FBJ-MuSV foci in tissue culture and, in the appropria
hosts, induced osteosarcomas typical of those induced b
FBJ-MuSV. These lines should be helpful in molecular st
dies of the origin of spontaneous sarcoma genomes in mic
(17 refs)

78-4460 **Characterization of Virus-like Particle
Released from the Hamster Cell Line CHO-K
after Treatment with 5-Bromodeoxyuridine.** (Eng) Manly, K
F. (Dept. Medical Viral Oncology, Roswell Park Memoria
Inst., Buffalo, NY, 14263); Givens, J. F.; Taber, R. L.; Zeige
R. F. *J Gen Virol* 39(3): 505-517; 1978.

The release of C-type viruslike particles from Chinese ham
ster ovary (CHO) K1 cells treated with 20 μg/ml of steri
5-bromodeoxyuridine (BUdR) was investigated. Few part
cles that had RNA, an associated DNA polymerase, and th
density typical of RNA tumor viruses were released by th
BUdR-induced cells. However, some immature C-type form
were observed by electron microscopy in partially purifie
preparations of DNA polymerase-containing particles fron
induced CHO cells. The max production of particle-boun
polymerase by BUdR-treated CHO cells was roughly 1% c
the production by a leukemia virus-infected mouse cell line
Similarly, uridine labeling suggested that the release c
RNA-containing particles was less than 1% of that from
similarly induced mouse cell line. It is concluded that simpl
biochemical measurements seriously overestimate the pro
duction of C-type particles by BUdR-induced CHO cells. (1

78-4461 **Induction of Type C RNA Virus from Culture
Rabbit Lymphosarcoma Cells.** (Eng) Bedigia
H. G. (Jackson Lab., Bar Harbor, ME, 04609); Fox, R. R
Meier, H. *J Virol* 27(2): 313-319; 1978.

C-type RNA virus(es) was readily released from prima
lymphosarcoma cell cultures of WH/J rabbits after inductic
with halogenated pyrimidines. The virus contained a
RNA-directed DNA polymerase and the p30 structural pr
tein. The rabbit virus RNA-directed DNA polymerase an
p30 protein shared antigenic homologies with other man
malian C-type oncornaviruses, but they also appeared to po
sess unique antigenic determinants. Normal rabbit liver co
tained DNA homologous to a ^{3}H-labeled complementa
DNA transcript of the rabbit viral genome, indicating th
C-type viral genetic information is present in at least th
WH/J strain of rabbits. (26 refs.)

78-4462 **The Influence of Virus Subgroup on the Epidemiology of Feline Leukemia Virus.** (Eng) Jarrett, O. (Dept. Veterinary Pathology, Univ. Glasgow, Glasgow, Scotland); Russell, P. H.; Hardy, W. D. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 25-28; 1978.

One hundred and forty-nine isolates of feline leukemia virus (FeLV) were analyzed for subgroup composition. FeLV occurred in three subgroups: FeLV-A present in every isolate, FeLV-B was common but was always associated with FeLV-A (FeLV-AB); and FeLV-C was rare and was found with FeLV-A (FeLV-AC) or with FeLV-AB (FeLV-ACB). FeLV-B was more common in cats with leukemia than in carrier cats, but the reverse was true for FeLV-A. However, there was no association between FeLV subgroup and any particular clinicopathological type of lymphosarcoma or leukemia. Among healthy cats from multicat households (MHC) yielding FeLV-AB, half of the cats yielded only FeLV-A. In MHC yielding FeLV-A, 28% of the cats were viremic, whereas in MHC yielding FeLV-AB, 53% were viremic. All neonatal cats infected by ip inoculation with 10^4 infectious units of FeLV-A developed FeLV-A viremia in about 10 days, and the viremia was persistent. Only 25% of neonatal cats infected with FeLV-B became viremic, and virus was not detectable until 6 to 12 mo after infection. The data suggest that the growth of FeLV-B in cats is restricted and that it is not transmissible by contact. When cats were infected simultaneously with FeLV-A and FeLV-B, the viruses acted independently to some extent, although the results indicated that the viruses may also have interacted. FeLV-A appears to enhance the growth of FeLV-B in cats and to be necessary for the transmission of FeLV-B. The preponderance of FeLV-AB over FeLV-A in MHC and in leukemic cats compared with carrier cats is probably due to infection with a high dose of virus and to a more long-standing infection. (5 refs.)

78-4463 **Evidence for the Possible Functional Involvement of Endogenous Type C Viral Gene Expression in Natural Malignancies of Domestic Cats.** (Eng) Roy-Burman, P. (Univ. Southern California Sch. Medicine, Los Angeles, CA, 90033); Niman, H. L.; Stephenson, J. R.; Gardner, M. B. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 452-455; 1978.

The role of C-type endogenous feline viruses in natural malignancies of the cat was studied by immunofluorescence using 60 histologically normal, 55 lymphoma, 9 sarcoma, and 14 carcinoma tissue specimens. A significantly higher level of RD-114 virus transcription and translation was noted in the lymphoma, sarcoma, and carcinoma tissue, compared with normal tissue. Lymphoma tissue from younger cats had significant levels of feline leukemia virus (FeLV) gene expression, but RD-114 virus expression was high in lymphomas of both young and old cats. Feline embryonal placenta and thymus also expressed viral genes. Although both RNA and p30 viral gene expressions were detected in the placenta, the marked elevation of RD-114 gene transcription in the thymus resembled the expression in most of the adult lymphoma tissues. The widespread occurrence of elevated levels of RD-114 virus-specific gene expression in the neoplastic tissues, independent of FeLV genome expression, suggests that the expression of certain functions of RD-114 virus may be involved in the development of spontaneous neoplasms in the domestic cat. (4 refs)

78-4464 **Transfection with Endogenous RD-114 Provirus of Cat Cells.** (Eng) Nicolson, M. O. (Univ. Southern California Sch. Medicine, Childrens Hosp., Los Angeles, CA); McAllister, R. M.; Okabe, H.; Gilden, R. V. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 139-140; 1978.

The transfection of human rhabdomyosarcoma TE-32 cells and dog D-17 sarcoma cells by endogenous provirus in cat cell DNA was examined. Only the DNA's of cells releasing RD-114 virus were infective for the human and dog cells, with minimum infectious doses ranging from 0.5 to 10 μg/ml. DNA from nonproducer cat fibroblasts and tissues did not transfect either cell line at doses up to 100 times the minimum infectious DNA dose. In virus-producing F100 osteosarcoma cells, proviral infectivity was covalently integrated in cell chromosomal DNA. All the cat cells contained 20 viral gene copies per haploid genome, which suggests that RD-114 provirus in productive cells differs in some qualitative characteristic from that in nonproductive cells. (5 refs)

78-4465 **RNA Tumor Virus Phosphoproteins: Subvirion Location of the Multiple Phosphorylated Species.** (Eng) Pal, B. K. (Dept. Pathology, Univ. Southern California Sch. Medicine, Los Angeles, CA, 90033); Roy-Burman, P. *Virology* 83(2): 423-427; 1977.

The structural location of the multiple phosphorylated

15,000-mol wt protein (pp15) of the endogenous RD-114 feline C-type virus was investigated. RD-114 cores were prepared by removal of the envelope components; the cores banded at a density of 1.23 g/cm^3. Guanidine-agarose chromatography showed that pp15 was present in the core structure. The data also indicated the presence of p30, p12, and p10 and protein kinase activity in the core preparation. A comparison of the content of multiple phosphorylated species of the pp15 derived from the core with that isolated from the whole virion demonstrated that all major phosphorylated species of RD-114 pp15 were located in the core structure. The finding of both protein kinase activity and the multiple phosphorylated protein species in the virus core suggests that biologically significant interactions occur between the enzyme and the core structural proteins. (24 refs)

78-4466 Endogenous Type C RNA Virus of Mink (*Mustela vison*). (Eng) Klement, V. (Dept. Pediatrics and Microbiology, Univ. Southern California Sch. Medicine, 1840 North Soto St., Los Angeles, CA, 90032); Dougherty, M. F.; Roy-Burman, P.; Pal, B. K.; Shimizu, C. S.; Rongey, R. W.; Nelson-Rees, W.; Huebner, R. J. *Virology* 85(1): 296-306; 1978.

The isolation and basic biological and biochemical characteristics of a new C-type RNA virus are described. The virus was isolated from a mink lung cell line (CCL64) that had been cocultivated with 5-bromodeoxyuridine-treated mouse spleen cells. The virus sedimented in sucrose density gradients at 1.13-1.17 g/ml, and the virus nucleocapsids sedimented at 1.19 g/ml. Immunofluorescence tests distinguished the new virus from murine C-type virus, and complement fixation tests distinguished it from the C-type viruses of rat, cat, mouse, baboon, and woolly monkey. The mink virus did not replicate in simian or bovine cells, but it did propagate in mouse, rat, cat, lamb, dog, and human cells. Two major species of RNA were identified: one species banded near the 70S region in sodium dodecyl sulfate-sucrose gradients, and the second species banded at about 4S. The protein profile was similar to that observed for other mammalian C-type viruses. The DNA complementary to the poly(A)-containing virion RNA hybridized about 72% with the RNA from virus-producing mink lung cells but not with the RNA from mouse cell lines or uninfected mink lung cells. The nucleotide sequences homologous to mink viral complementary DNA were found in mink cell DNA from both virus-producing and nonproducing cells, but not in mouse, rat, or feline DNA. The data indicate that the new virus is an endogenous mink C-type virus, although its biological significance in the diploid mink genotype remains unknown. (33 refs)

78-4467 **Detection of C-Type Virus in Immunologically Reactive Ovine Lymph Nodes.** (Eng) Atkins, G. J. (Dept. Microbiology, Trinity Coll., Dublin 2, Ireland); Moynihan, M.; Arbuthnott, E.; Hartigan, P. J. *FEMS M* *crobiol Lett* 2(2): 75-77; 1977.

Electron microscopy of a reactive lymph node from a shee with a scab mite (*Psoroptes communis*) infection revealed th presence of C-type virus particles. To confirm this observation, lymph nodes from this and two other infested sheep an from five normal sheep were studied for reverse transcriptas activity. This activity was consistently observed in the lymp node culture fluids from 2/3 mite-infested sheep; no activit was observed in the culture fluids of lymph nodes from fiv normal sheep. In the infested sheep, reverse transcriptase activity was low compared with the activity in fluids from cell producing murine sarcoma/leukemia virus, but it approached the level observed in cells producing bovine leukemia. This virus could either be exogenous or endogenous and activated by a persistent immune respons (8 refs)

78-4468 **Susceptibility of Cattle to Bovine Leukemi Virus Infection by Various Routes of Exposur** (Eng) Van der Maaten, M. J. (P. O. Box 70, United State Dept. Agriculture, Agricultural Res. Service, Natl. Anima Disease Center, Ames, IA, 50010); Miller, J. M. *In: Advance in Comparative Leukemia Research 1977. Proceedings of th VIIIth International Symposium on Comparative Research o Leukemia and Related Diseases, held in Amsterdam, Th Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilger J.; Yohn, D. S., eds. (New York: Elsevier/North Hollan Biomedical Press): 503 pp.; 29-32; 1978.

The routes by which bovine leukemia virus (BLV) is mos likely to gain access to susceptible tissues and initiate ne infections were studied in BLV-negative calves and cows. A of six newborn calves exposed to BLV po developed persiste infections, compared with only one of two 3-day-old calv and neither of two 3-wk-old calves exposed in the same manner. Both 3-mo-old calves exposed to an aerosol of cell-fre BLV developed infections, but only one of two 2- to 3-mo-ol calves exposed by the intranasal instillation of infected WB developed an infection. Four of six mature cows exposed t BLV by the instillation of infected WBC into their reproductive tract developed antibody responses indicative of infection. All five calves inoculated id with infected periphera blood WBC developed BLV infections, as did all three calve inoculated id with cell-free material. The results suggest tha the skin may play an important role in the horizontal transmission of BLV infections. (6 refs.)

78-4469 **Natural Mode of Transmission of the Bovin Leukemia Virus: Role of Bloodsucking Insect** (Eng) Bech-Nielsen, S. (Dept. Epidemiology and Communit Health, Sch. Veterinary Medicine, Louisiana State Univ., Ba ton Rouge, LA, 70803); Piper, C. E.; Ferrer, J. F. *Am J Vet Res* 39(7): 1089-1092; 1978.

The development of bovine leukemia virus (BLV) infection was studied in 14 noninfected young adult cattle exposed to 25 to 30 BLV-infected cows in a 0.5-hectare area. Of seven cattle exposed between July and August, four showed signs of BLV infection by October, and the remaining three were infected by November. All seven cattle exposed in February remained negative for at least 3 mo, and only one was positive after 6 mo exposure. However, four of the cattle were infected by October. Approx 1.8 x 10^6 BLV-infected lymphocytes (50% viability) were recovered from the midgut of at least 35 engorged tabanids that had been allowed to feed on a BLV-infected cow. Numerous syncytia were observed in indicator bovine embryonic spleen cells inoculated with these lymphocytes or with lymphocytes obtained directly from the infected cow. The data support the contention that bloodsucking insects play a major role in the spread of BLV. (28 refs.)

78-4470 **Etiologic Association of Bovine Leukemia Virus with Lymphosarcoma of Domestic Cattle.** (Eng) Devare, S. G. (NCI, NIH, Bethesda, MD, 20014); Stephenson, J. R. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 231-232; 1978.

Radioimmunoassays were developed for detecting antibody directed against the major 24,000-dalton structural protein (p24) and the 51,000-dalton envelope glycoprotein (gp51) of bovine leukemia virus (BLV). These radioimmunoassays, in which ^{125}I-labeled p24 and gp51 are used, are much more sensitive and reliable for the detection of BLV infection in domestic cattle than previously described serologic techniques. Sera from 100% of adult cattle tested with clinically diagnosed lymphosarcoma exhibited high-titered antibody against both p24 and gp51. In contrast, sera from cattle in a BLV-negative herd lacked detectable antibody to BLV. Approx 6,000 animals from 22 states were tested for antibodies to ^{125}I labeled BLV p24. The frequency of animals exhibiting high titers of p24 antibody varied from a low of 2% to $>40\%$ in certain states. (3 refs)

78-4471 **Direct Syncytial Assay for the Quantitation of Bovine Leukemia Virus.** (Eng) Benton, C. V. (Viral Oncology Program, Natl. Cancer Inst. Frederick Cancer Res. Center, Frederick, MD, 21501); Soria, A. E.; Gilden, R. V. *Infect Immun* 20(1): 307-309; 1978.

A direct quantitative bioassay for bovine leukemia virus (BLV) was developed based on cell fusion following BLV infection of F81 cells, a feline sarcoma-positive leukemia-negative (S+L-) cell line. F81 cells were incubated for 24 hr and BLV was added to the incubation mixture. After 16 days of infection, the plates were fixed and stained with methylene blue and carbol fuchsin. Using this assay system, BLV infection resulted in large, multinucleated syncytia that retained less stain than the surrounding monolayer. These fused cells were distributed evenly throughout the monolayer. Titration of the virus resulted in a reproducible linear decrease in syncytia that was directly proportional to the virus dilution, consistent with a one-hit response. The assay was specific for BLV. Viruses from several subprimate [Rauscher murine leukemia virus (MuLV), mink cell focus-inducing MuLV, and mouse mammary tumor virus] and primate (baboon leukemia virus and Mason-Pfizer monkey virus) species were tested, but they did not produce a morphological change similar to that seen with BLV. 78-4472 **Physico-chemical and Biological Properties of Viruses Isolated from Cultures of Primary Human Tumors.** (Rus) Shevlyagin, V. Ya. (N. F. Gamaleia Inst. Epidemiology and Microbiology, Moscow, USSR); Klenova, A. V.; Borodina, N. P.; Chizhevskaia, V. I.; Voskoboinik, A. D.; Eremina, L. A. *Vestn Akad Nauk SSSR* (5): 73-78; 1978.

Viruses isolated from a human embyro fibroblast culture transformed by a cell-free extract of human malignant paranglioma cells (transformed culture 63) were identified. Incubation of the culture with ^{3}H-uridine or ^{3}H-thymidine and subsequent centrifugation in a sucrose gradient showed the presence of DNA at a density of 1.23 g/ml and RNA at a density of 1.16-1.8 g/ml. The RNA-containing virus showed no reverse transcriptase or hemagglutinating activity. The DNA-containing virus showed hemagglutinating activity with guinea pig RBC and human blood group O RBC. Electron microscopically, the RNA-containing virus was classified as an orthomyxovirus, the DNA-containing virus as a papovavirus. Incubation of a human embryo brain cell culture with a cell-free extract of transformed culture 63 induced cytolytic changes in 19/74 experiments: in 17 experiments, these changes disappeared with culturing (abortive transformation), but in 2 experiments the changes became stable. (15 refs)

78-4473 **Inverted Repetitive Sequences in Human Papilloma Virus 1 (HPV-1) DNA.** (Eng) Gissmann, L. (Zentrum fur Hygiene, Hermann-Herder-Strasse 11, 78 Freiburg im Breisgau, W. Germany); zur Hausen, H. *Virology* 83(2): 271-276; 1977.

The identification by electron microscopy of two pairs of inverted repetitive (palindromic) sequences in the human papilloma virus 1 (HPV-1) genome is reported. The two sequences were designated IR 1a/b and IR 2a/b, respectively. The distance between IR 1a and IR 1b corresponded to 0.8 x 10^6 in mol wt, but IR 2a and IR 2b were separated by a DNA stretch of 0.4 x 10^6. The positions of the sequences in the HPV-1 genome were mapped by examining the DNA cleaved by *Bam*HI or *Eco*RI endonucleases. The mol wts of these sequences were determined to be 0.11 and 0.10 x 10^6, but it was not determined which value corresponded to IR 1a/b and which corresponded to IR 2a/b. (13 refs)

78-4474 **Search for Evidence of Papovavirus Involvement in Human Cancer.** (Eng) Takemoto, K. K. (Natl. Inst. Allergy and Infectious Diseases, NIH, Bethesda, MD): Solomon, D.; Israel, M.; Howley, P. M.; Khoury, G.; Aaronson, S. A.; Martin, M. A. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Disease, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York Elsevier/North Holland Biomedical Press): 503 pp.; 260-263; 1978.

The involvement of BKV and JCV papovaviruses in human neoplasia was examined using (1) tests for the presence of intranuclear T antigen in tumor cell lines, (2) tests of the serum from cancer patients for T antibody, and (3) analyses of tumor cell DNA for viral sequences. Fifty-five different tumor lines, including those derived from the brain and kidney, were tested for the presence of T antigens against BKV and JCV. All were negative for T antigen. Sera from patients with kidney, brain, bladder, and esophageal tumors were tested for T-antibody to BKV and JCV, and all were found to be negative. Fifteen tumor cell lines that were negative for T antigens were also examined for BKV DNA sequences; all tumor lines were negative for BKV sequences. Analyses with JCV DNA were not performed because of the lack of suitable cell systems for growing JCV. If there is a relationship between BKV or JCV and human cancer, the mechanism of tumor induction does not conform to known models of papovavirus-induced transformation. (9 refs)

78-4475 **Virus-Specific Early RNA in 3T6 Cells Infected by a tsA Mutant of Polyoma Virus.** (Eng) Cogen, B. (Tumor Virology Lab., Salk Inst., San Diego, CA, 92112). *Virology* 85(1): 222-230; 1978.

The transcription of stable early polyoma-specific cytoplasmic RNA in mouse 3T6 cultures infected by wild-type polyoma virus or by a polyoma tsA mutant (tsA25E) was studied. 3T6 cultures infected by the mutant accumulated approx 20 times more virus-specific early RNA than did cultures infected with wild-type virus at both 32 and 39 C. This abnormal accumulation was observed when the infection was confined to the early stage by treatment of the infected cultures with cytosine arabinoside to block viral DNA replication. The abnormal accumulation was also observed 40 to 60 hr postinfection, and virus-specific early RNA continued to accumulate in the tsA25E mutant-infected cultures that had been shifted from the permissive to the nonpermissive temperature late in infection to block viral DNA replication. Mixed infection of 3T6 cultures by wild-type virus and tsA25E did not result in an enhanced accumulation of virus-specific early cytoplasmic RNA. The results suggest that the A gene product of polyoma regulates the transcription of early RNA and that the wild-type A-gene product overcomes the effect of the temperature-sensitive A-gene product. (34 refs)

78-4476 **Induction of Peripheral Neuroblastomas in Syrian Hamsters after Injection as Neonate with JC Virus, a Human Polyoma Virus.** (Eng) Varakis J. (Dept. Pathology, Univ. Southern Alabama, Mobile AL, 36688); ZuRhein, G. M.; Padgett, B. L.; Walker D. L. *Cancer Res* 38(6): 1718-1722; 1978.

Newborn Syrian hamsters were inoculated intraocularly with partially purified JC virus (0.02 ml of viral material containing 5,120 hemagglutinating units), a human polyoma virus, and tumor induction was studied. Neuroblastomas developed in 10/31 hamsters after a latent period of 6-11 mo. No tumors were noted in controls. Primary tumors were noted in the abdominal cavity (6), pelvis (1), and neck and mediastinum (3). One tumor arose from the adrenal gland. Metastases to the liver, bone marrow, and lymph nodes were observed. Two of the neuroblastomas were transplanted serially in weanling hamsters, and a tissue culture line (HJCN-1) was established from one of the transplanted tumors. T antigen was detected in 3/5 primary tumors tested and in the transplanted tumors. Antibody against T antigen was detected in the sera of 5/6 animals with neuroblastomas. A neuroblastoma was also noted in an animal inoculated sc and ip with JC virus; it was transplanted serially five times in weanling hamsters. Some animals given sc inoculations of this neuroblastoma exhibited visceral and lymph node metastases. (12 refs)

78-4477 **Effects of BK Virus Infection on Primary Cultures of Rodent and Primate Cells.** (Eng) Greenlee, J. E. (Dept. Neurology, Univ. Virginia Medical Center Charlottesville, VA, 22901); Narayan, O.; Johnson, R. T *Proc Soc Exp Biol Med* 158(3): 437-441; 1978.

The effect of BK virus (BKV) at high multiplicity was studied on cultures of hamster, rat, monkey, and human cells. BKV produced multiple transforming events in rodent cells without evidence of replication of infectious virus. Rhesus monkey choroid plexus cells were not susceptible to the virus. Of the three human cell types studied, colloid cyst cells and human embryo kidney, both epithelial cell types, developed lytic infection without evidence of cell transformation. Fibroblastic human fetal skin and muscle cells also developed lytic infection. Although 15%-20% of surviving cells showed T antigen, other criteria for transformation were not met. Approx 90%-100% of transformed rodent cells exhibited T antigen. BKV could be recovered only from rat cells and not from hamster cells. Interestingly, rat embryo cells are among the few cell types from which recovery of infectious virus has been reported after transformation by polyoma virus. BKV-transformed rat cells could not be transplanted, and transformed hamster cells were poorly oncogenic for hamsters. Immunosuppression was required for tumor production in newborns, and inoculation into the cheek pouch, an immunologically privileged site, was required in adults. These data support the hypothesis that the poor oncogenicity of BKV in vivo may represent at least in part, an immunological recognition and rejection of transformed cells by the host. (21 refs.)

78-4478 **Metastatic Properties, Immunogenicity and Cell Surface Sialylation of Tumor Cell Lines Derived from a Polyoma-induced Rat Renal Sarcoma (Meeting Abstract).** (Eng) Salk, P. (Salk Inst. Biological Studies, San Diego, CA, 92112); Yogeeswaran, G. *Fed Proc* 37(6): 1760; 1978. (no refs)

78-4479 **Polyoma Virus Has Three Late mRNA's: One for Each Virion Protein.** (Eng) Siddell, S. G. (Institut fur Virologie und Immunobiologie der Universitat Wurzburg, D8700 Wurzburg, W. Germany); Smith, A. E. *J Virol* 27(2): 427-431; 1978.

Polyoma virus messenger RNA (mRNA), isolated from the cytoplasm of 3T6 cells late after infection and purified by hybridization to *Hpa*II fragment 3 of polyoma virus DNA, was separated on 50% formamide-containing sucrose density gradients, and the fractionated RNA was recovered and translated in vitro. Analysis of the cell-free products showed that the minor virion protein VP3 was synthesized from an mRNA sedimenting at approx 18S between the 19S VP2 mRNA and the 16S VP1 mRNA. Other experiments showed that the VP2 and VP3 can be labeled with formyl methionine from initiator transfer RNA. It is concluded that there are three late polyoma virus mRNA's, each directing the synthesis of only one viral capsid protein. (25 refs.)

78-4480 **The Effect of Neonatal Thymectomy on the Growth Kinetics of a Virus-induced Renal Sarcoma of the Rat.** (Eng) Lang, W. (Dept. Pathology, Medical Sch., Hannover, W. Germany); Zobl, H.; Georgii, A. *Eur J Cancer* 14(4): 431-437; 1978.

The growth of polyoma virus-induced renal sarcomas in normal and neonatally thymectomized Wistar rats was compared. The animals were inoculated sc with 0.3 ml of a virus suspension ($TCID_{50}$ 10^6 or 10^7) within 24 hr after birth. A total of 41 unilateral and 65 bilateral renal tumors developed in 149 nonthymectomized (NT) rats; 17 unilateral and 44 bilateral sarcomas were found in 77 thymectomized rats. In both groups, there was an increase in tumor wt up to 50 days of age; thereafter, a slowdown of growth or even an incipient regression was observed. Tumor doubling time was 110 hr in the NT group and 76 hr in the thymectomized group. The quotient of absolute cell loss rates (loss in the proliferative compartment/loss in the nonproliferative compartment) was 70 in 30-day-old NT animals, 1.7 in 30-day-old thymectomized animals, 1.3 in 50-day-old TN animals, and 0.7 in 50-day-old thymectomized animals. The reduction of doubling time in tumors of thymectomized rats was due to an increase of the proliferative fraction despite increased cell loss rates. (39 refs)

78-4481 **Neoplastic Transformation of Hamster Brain Cells In Vitro by Polyoma Virus.** (Eng) de Micco, C. (Laboratoire de Neuropathologie, Faculte de Medecine, 27 Bd. Jean Moulin, 13005 Marseilles, France); Tripier, M. F.; Hassoun, J.; Lipcey, C.; Meyer, G.; Toga, M. *Int J Cancer* 21(4): 516-522; 1978.

The in vitro transformation of a line of hamster brain cells (HCxPy) by polyoma virus is reported. The primary cultures were initiated from newborn Syrian hamster cerebral hemispheres. Foci of transformed cells first appeared 120 days after viral infection, during the fourth passage in vitro. Three transformed cell types grew simultaneously: (1) small, stellate, triangular or multipolar cells with long, thin branched processes; (2) large, flat, often multinucleated cells; and (3) cells intermediate between these two types. About 10% of the cells were positive for polyoma-specific nuclear antigen and 60% to 90% were positive for polyoma-specific surface antigen. HCxPy cells were as effective as polyoma virus in protecting hamsters against challenge by a polyoma-induced transplantable sarcoma. Sc and intracranial injection of these cells into hamsters produced tumors that were serially transplanted in adult animals. All HCxPy cells were positive for brain-specific S 100 protein. Microscopic examination revealed H-type virus particles in some cells. The cells had glial features both in vivo and in vitro. The morphologic and immunohistochemical evidence indicates that the HCxPy cell line is neuroglial in nature. (30 refs)

78-4482 **Primase Initiates Okazaki Pieces During Polyoma DNA Synthesis.** (Eng) Eliasson, R. (Dept. Biochemistry I, Medical Nobel Inst., Karolinska Inst., S-104 01 Stockholm, Sweden); Reichard, P. *Nature* 272(5649): 184-185; 1978.

Study of an RNA that initiates Okazaki pieces (iRNA) during polyoma DNA synthesis revealed that iRNA is not synthesized by any of the known RNA polymerases. Instead, a mammalian enzyme, primase, is involved in catalyzing the initiation of Okazaki pieces of polyoma DNA. The primase can substitute deoxynucleotides for ribonucleotides, and, thus, it resembles the dnaG product of *Escherichia coli.* The mammalian enzyme appears to prefer ribonucleotides for primer formation, but in the presence of equimolar concentrations of ribo- and deoxynucleotides, a certain amount of misincorporation of deoxynucleotides can also take place. (12 refs)

78-4483 **Transformation of African Green Monkey Kidney Cells with the RF Strain of Human Papovavirus BKV.** (Eng) Bradley, M. K. (Dept. Microbiology, State Univ. New York, Upstate Medical Center, Syracuse, NY, 13210); Dougherty, R. M. *Virology* 85(1): 231-240; 1978.

The establishment of a stable transformed primate cell line by infection of semipermissive African green monkey kidney (AGMK) cells with the RF strain of human papovavirus BKV is described. The infected cultures showed slow cytopathic effects, and the surviving cells were cultured in the presence of virus-neutralizing antibody. This resulted in the emergence of a stable cell line (MRF-325) that is presently at the 100th tissue culture generation. The transformed line showed no tendency to form multiple layers. The monolayers were composed of small epithelioid cells interspersed with nests of larger cells and occasional multinucleate giant cells. Compared with normal AGMK cells, the MRF-325 cells attained a higher saturation density and displayed a decreased serum requirement for growth. They formed colonies in soft agar and multiplied in suspension culture. No infectious virus particles were isolated by cocultivation or fusion of MRF-325 with permissive human embryo kidney cells, and no virion antigens were detected. Papovavirus T antigen and U antigen were detected in 100% of the MRF-325 nuclei by immunoperoxidase staining. Normal and MRF-325, but not AGMK, cells were relatively resistant to challenge with simian virus 40 (SV40). MRF-325 cells supported high levels of human adenovirus type 5 replication compared with primary AGMK cells. Thus, RFV appears to provide a helper effect for adenovirus replication in AGMK cells similar to that observed with SV40. The data confirm that the oncogenic potential of human papovaviruses extends to primate cells. (48 refs)

78-4484 **Transcription and Coupled Transcription-Translation of Cloned DNAs in *Xenopus* Oocytes (Meeting Abstract).** (Eng) Mertz, J. E. (McArdle Lab. Cancer Res., Madison, WI); Gurdon, J. B.; De Robertis, E. M. *Miami Winter Symp* 14: 269; 1977. (no refs)

78-4485 **Binding of Dextran Sulfate by Virus-transformed Cells, with Reference to Altered Growth Behavior by Its Treatment.** (Eng) Goto, M. (Dept. Pharmacology, Pharmaceutical Inst., Aramaki aza Aoba, Sendai 980, Japan); Hori, K.; Ozawa, H.; Goto, K.; Sato, H. *Gann* 69(1): 31-37; 1978.

The binding of ^{3}H-dextran sulfate to untransformed (3T3) and virus-transformed (SV3T3) fibroblasts was studied in relation to the altered growth of transformed cells by this treatment. SV3T3-R5 cells, SV3T3 cells that were insensitive to dextran sulfate treatment, were also used. Liquid scintillation counting indicated that the rate of dextran sulfate binding to SV3T3 cells was dose-dependent. Autoradiography indicated that there was no difference in the binding capacity of dextran sulfate among 3T3, SV3T3, and SV3T3-R5 cells. The rate of binding proceeded linearly during the first 10 hr and then declined. Autoradiography of 0.3- to 0.5-μm sections of SV3T3 cells indicated that after 1 hr, all the dextran sulfate was located on the cell surface. After 8 hr, radioactivity was detected in the cytoplasm, and after 24 hr, it was detected in the nucleus. The localization of dextran sulfate was similar in 3T3 cells. The binding of dextran sulfate on SV3T3 cells was independent of the presence of calf serum in the medium. These findings suggest that the amount of dextran sulfate bound to transformed cells is not the main cause of the altered growth of these cells. (11 refs)

78-4486 **Involvement of DNA Polymerase α in Simian Virus 40 DNA Replication.** (Eng) Edenberg, H. J. (Dept. Biochemistry, Indiana Univ. Sch. Medicine, Indianapolis, IN, 46202); Anderson, S.; DePamphilis, M. L. *J Biol Chem* 253(9): 3273-3280; 1978.

Replicating simian virus 40 (SV40) chromosomes that were capable of continuing DNA synthesis in vitro were partially separated from mature SV40 chromosomes on sucrose gradients and analyzed for DNA polymerase activities. The DNA polymerases were extracted with salt, fractionated by 2-(diethylamino)ethylcellulose chromatography, and assayed under conditions selective for each polymerase. Both DNA polymerase α and DNA polymerase γ were found, although the former accounted for about 95% of the total DNA polymerase activity. The amounts of both enzymes were severalfold higher in replicating chromosomes than in mature chromosomes. DNA polymerase β was not found associated with SV40 chromosomes. These experiments were complemented by a study of the inhibition of DNA synthesis by $2'$:$3'$-dideoxythymidine $5'$-triphosphate (d_2TTP). SV40 DNA synthesis in nuclei isolated from infected CV-1 cells, in a soluble nuclear extract, or in replicating SV40 chromosomes was resistant to d_2TTP inhibition. DNA polymerase α was nearly as resistant to d_2TTP inhibition as were the in vitro DNA replication systems. DNA polymerases β and γ, however, were extremely sensitive to inhibition by d_2TTP. In the presence of d_2TTP, Okazaki fragments continued to be synthesized and joined to long chains of nascent DNA, and mature viral DNA forms were produced. Thus, virtually all the DNA synthesis observed in SV40 chromosomes replicating in vitro is performed by DNA polymerase α. (55 refs)

78-4487 **Simian Virus 40 as a Cloning Vehicle in Mammalian Cells.** (Eng) Hamer, D. H. (Lab. Molecular Genetics, Natl. Inst. Child Health and Human Development, NIH, Bethesda, MD, 20014). *Miami Winter Symp* 14: 37-47; 1977.

The in vitro generation of a simian virus 40 (SV40) transducing virus is described. An 870 base pair (bp) fragment of *Escherichia coli* DNA was ligated to a 3,700 bp fragment of SV40 DNA produced by cleavage with *Hpa*II and *Eco*RI. The recombinant molecules, which retained the early viral gene *A* but lacked sequences necessary for late gene expression, were propagated as virus by coinfection with a conditional lethal SV40 early gene mutant as helper. Preliminary experiments indicate that this system can be used to propagate foreign DNA fragments in productively infected, permissive monkey cells and in transformed, nonpermissive cells. (20 refs)

78-4488 **Association of DNA Polymerase α with Highly Purified Replicating Simian Virus 40 (SV40) Chromosomes (Meeting Abstract).** (Eng) Tsubota, Y. (Roswell Park Memorial Inst., Buffalo, NY, 14263); Waqar, M. A.; Spotila, L.; Kowalski, D.; Eddy, M.; Evans, M. *Fed Proc* 37(6): 1603; 1978. (20 refs)

78-4489 **Presence of Free Viral DNA in Simian Virus 40-Transformed Nonproducer Cells.** (Eng) Daya-Grosjean, L. (Institut de Recherches Scientifiques sur le Cancer, 94800 Villejuif, France); Monier, R. *J Virol* 27(2): 307-312; 1978.

Extracts from several simian virus 40 (SV40)-transformed nonproducer cells were prepared by the hot-phenol procedure normally used to extract cellular RNA. The cells were TSV-5 clone 2 Syrian hamster cells, CHK-SVLP clone 5.1 Chinese hamster cells, MKSV clone 11D mouse cells, V5 F4 clones 1 and 4 rat kidney cells, and V11 F1 clones 1 and 3 rat lung cells. All the extracts contained SV40 infectious units. Some of the infectious units were identified as SV40 form I DNA molecules. The results of reconstruction experiments suggest that SV40 form I DNA is extractable by the hot-phenol procedure because of its fast renaturation rate. Two hypotheses are proposed with respect to the origin of the free viral DNA: (1) spontaneous excision could occur at very low frequency in the transformed cells; (2) viral DNA replication might be initiated repeatedly at the level of an integrated copy, resulting in free linear molecules produced by branch migration. The significance of the presence of free viral DNA in nonproducer transformed cells is discussed. (16 refs.)

78-4490 **DNA Polymerase α Is Associated with Replicating SV40 Nucleoprotein Complexes.** (Eng) Otto, B. (Fachbereich Biologie, Univ. Konstanz, D-7750 Konstanz, W. Germany); Fanning, E. *Nucleic Acids Res* 5(5): 1715-1728; 1978.

Replicating simian virus 40 (SV40) nucleoprotein complexes were isolated from CV-1 cells infected with the Rh911 strain of SV40 and examined for the presence of DNA polymerase α to determine if this polymerase is the one responsible for cellular DNA replication. The complexes were extracted from the nuclei of infected cells and fractionated on neutral sucrose density gradients. Complexes containing replicating SV40 DNA (95S) were separated from those containing closed circular supercoiled viral DNA (75S). DNA polymerase activity was associated with the replicating nucleoprotein complexes but not with the slower sedimenting complexes. This polymerase activity coprecipitated with the nucleoprotein complexes in the presence of $MgCl_2$ and remained associated with the 95S complexes. It was identified as the α form on the basis of its sedimentation behavior, optimum salt concentration, and sensitivity to N-ethylmaleimide. DNA polymerase γ activity was also detected in the complexes, but not that of DNA polymerase β. These findings provide additional support for the role of the α polymerase in SV40 replication. It is not known, however, whether both the α and γ forms are required for replication. (28 refs)

78-4491 **Canine Kidney Cells: I. Neutral Lipids, Phospholipids and Fatty Acids of SV40 Transformed Canine Kidney Cells in Suspension and Monolayer Culture.** (Eng) Hougland, A. E. (Dept. Health Sciences, East Tennessee State Univ., Johnson City, TN, 37601); Gaush, C. R.; Hougland, M. W. *Growth* 42(1): 59-69; 1978.

Studies were undertaken to determine differences in lipid composition between simian virus 40 (SV40)-transformed canine kidney whole cells and their plasma membranes and to determine the effects of monolayer and suspension culturing on the lipid content of whole cells and their plasma membranes. The plasma membranes from monolayer and suspension cultures of transformed cells were isolated by the Warren fluorescein-mercuric acetate technique. Free cholesterol was the major neutral lipid extracted from the whole cells and plasma membranes of all these cultures. Triglyceride increased about 6- to 50-fold in suspension-grown whole cells and their plasma membranes, compared with those from monolayer cultures. The micromoles of total neutral lipids and phospholipids were elevated in the plasma membranes from monolayer cultures compared with whole cells from monolayer cultures, but they were similar in both suspension cultures. The distribution of fatty acids in the major lipid classes of plasma membranes and whole cells generally followed the composition of calf serum used in the culture media. (23 refs)

78-4492 **Okazaki Pieces Grow Opposite to the Replication Fork Direction During Simian Virus 40 DNA Replication.** (Eng) Kaufmann, G. (Biochemistry Dept., Weizmann Inst. Science, Rehovot, Israel); Bar-Shavit, R.; DePamphilis, M. L. *Nucleic Acids Res* 5(7): 2535-2545; 1978.

In vitro-synthesized simian virus 40 (SV40) nascent DNA chains of $<$ 200 nucleotides (Okazaki pieces) were hybridized to an excess of single-stranded DNA fragments of unidirectional fork polarities in order to determine the fork polarity of the Okazaki pieces. SV40 replicating DNA was pulse-labeled with α-^{32}P-deoxy ATP by an acellular DNA replication system. The Okazaki pieces were then isolated from the denatured replicating DNA by electrophoresis using a polyacrylamide gel column. The purified Okazaki pieces were hybridized to separated strands of Bgl$_1$ + Hpa$_1$ SV40 DNA restriction fragments immobilized on nitrocellulose filters. Only strands with the polarity of the DNA replication fork direction hybridized with the Okazaki pieces. The results are consistent with semidiscontinuous DNA synthesis in SV40, in which Okazaki pieces are synthesized only against the DNA replication fork direction. (18 refs.)

78-4493 **Stimulation of RNA Synthesis in Isolated Nucleoli by Preparations of Simian Virus 40 T Antigen.** (Eng) Whelly, S. (Univ. Nebraska Medical Center, Obstetrics Gynecology Res. Lab., Conkling Hall, 42nd and Dewey Ave., Omaha, Nebraska, 68105); Ide, T.; Baserga, R. *Virology* 88(1): 82-91; 1978.

The ability of simian virus 40 (SV40) tumor (T) antigen to directly stimulate RNA synthesis in isolated rat liver nucleoli was studied. Both partially and highly purified SV40 T antigen preparations stimulated the incorporation of ^{3}H-uridine triphosphate into the RNA of isolated nucleoli. The stimulation was largely α-amanitin-resistant, and it appeared that the product of nucleolar RNA synthesis included at least some preribosomal RNA sequences. T antigen was also partially purified from Chinese hamster cells transformed by the temperature-sensitive *ts*A mutant of SV40. The complement-fixing and RNA-stimulating activities of the *ts*T antigen, but not those of the T antigen from wild-type SV40-transformed cells, were inactivated by preincubation at 50 C. The stimulation of nucleolar RNA synthesis by three different preparations of T antigen was proportional to the complement-fixing activity of the preparation. Cellular RNA synthesis was also stimulated when quiescent 3T3 cells were infected with wild-type SV40. The results strongly suggest that one of the sites of action of SV40 T antigen may be at the level of transcription of nucleolar DNA. (49 refs.)

78-4494 **Inhibition of Postreplication Repair and the Enhancement of Induction of SV40 Virus from Transformed Hamster Kidney Cells.** (Eng) Zamansky, G. B. (Infectious Disease Unit, Massachusetts General Hosp., Boston, MA, 02114); Little, J. B.; Black, P. H.; Kaplan, J. C. *Mutat Res* 51(1): 109-119; 1978.

The effect of caffeine on the postreplication repair of UV-damaged DNA in untreated and mitomycin C-treated simian virus 40 (SV40)-transformed hamster kidney cells was studied. Exposure to 0.5, 1.0, or 2.0 mM caffeine after UV irradiation dramatically inhibited postreplication repair, preventing the cellular DNA molecules from reaching parental size. Caffeine decreased the survival of cells previously exposed to various concentrations of mitomycin for 8 hr, although caffeine in the absence of mitomycin C had no effect on cell survival. The level of virus induction was increased two- to threefold in cells grown for 8 hr in medium containing 0.025 or 0.05 μg/ml mitomycin C. At higher mitomycin C concentrations, virus yields decreased in the presence of caffeine. It is postulated that the persistence of gaps in UV-irradiated DNA, caused by the presence of caffeine, results in the enhancement of SV40 induction. (33 refs.)

78-4495 **Interference with Simian Virus 40 DNA Replication by Adenovirus Type 2 During Mixed Infection of Monkey Cells.** (Eng) Van Roy, F. (Lab. Molecular Biology, State Univ. Ghent, Ledeganckstraat, 35, B-9000 Ghent, Belgium); Fiers, W. *J Virol* 27(2): 275-287; 1978.

The inhibiting effect that human adenovirus (Ad) superinfection exerts on simian virus 40 (SV40) DNA replication was examined in detail, using established African green monkey kidney (AGMK) cell lines and SV40 strain 776. In AGMK cells coinfected with SV40 and human Ad2, the Ad2 interfered strongly with SV40 DNA biosynthesis. This interference was found to be a reproducible, delicately controlled phenomenon that was proportional to the multiplicity of infection of Ad and dependent on the active expression of the Ad genome. A pulse-chase experiment showed that Ad interference was not due to degradation of newly synthesized SV40 DNA molecules. Several early events of SV40 infection (adsorption, penetration, undercoating, induction of cellular DNA synthesis, and enhancement of Ad infection) were not markedly influenced by Ad-mediated interference. It is unlikely that interference is simply due to competition between SV40 and Ad for metabolites, enzymes, or replication sites, as interference by a constant amount of Ad is gradually suppressed as more SV40 is used in coinfections. The interference effect could also be partially neutralized by an increase in the time interval between SV40 infection and Ad coinfection. It was concluded that the interference was due to the activity of an Ad early gene product. The detailed mechanism of this Ad interference remains unclear. (28 refs.)

78-4496 **Decrease of Collagen Biosynthesis Ability of Rat Kidney Fibroblasts Transformed with SV-40 Virus.** (Eng) Bankowski, E. (Dept. Biochemistry, Inst. Biochemistry and Medical Analytics, Bialystok, Poland); Rzeczycki, W.; Nowak, H. K.; Jodczyk, K. J. *Mol Cell Biochem* 20(2): 77-84; 1978.

The effects of simian virus 40 (SV40) transformation on the ability of newborn rat kidney fibroblast cultures to produce collagen were determined. Both normal and transformed fibroblasts incorporated radioactive proline into their proteins. In normal cells, about 17% of the prolyl residues that were incorporated into the medium, 15% of the proteins extracted with 1 M NaCl, and about 5% of those bound with the cell sediment were hydroxylated. However, only about 1% of the proline-containing proteins synthesized by the transformed cells were hydroxylated. Study of the proline-containing proteins synthesized by the cells indicated that the transformed cells produced a significantly lower amount of collagenase-sensitive hydroxyproline-containing material than normal cells. Attempts to stimulate hydroxylation of the propyl residues indicated that insufficient activation of propylhyuroxylase in the transformed cells was not a cause of this phenomenon. Further study indicated that there were no collagenous proteins in the culture medium or cell extract. It is concluded that transformation of rat kidney fibroblasts by SV40 causes a loss or decrease in their ability to synthesize collagen. (17 refs.)

78-4497 **Localization of the 5′ Terminus of Late SV40 mRNA.** (Eng) Haegeman, G. (Lab. Molecular Biology, Univ. Ghent, Ledeganckstraat 35, 9000 Ghent, Belgium); Fiers, W. *Nucleic Acids Res* 5(7): 2359-2371; 1978.

A cap-containing T_1 oligonucleotide of simian virus 40-specific, cytoplasmic late messenger RNA (mRNA) was isolated by chromatography on acetylated dihydroxyboryl cellulose followed by fingerprinting, and it was identified by subsequent analysis with several nucleases. Its structure was determined to be 7m-G(5′)ppp(5′)-m-AmpU(m)pUp(Up,Cp)ApGp. This oligonucleotide constitutes the major 5′ terminus of both the 16S and 19S late mRNA species. Assuming that viral mRNA caps are derived from a 5′-terminal triphosphate or diphosphate, these results mean that late transcription is initiated mainly at nucleotide L 308. The cap is followed by a contiguous leader sequence that is at least 194 nucleotides long. The sequence of the leader of the viral late RNA's in this region corresponds exactly to a continuous sequence of the DNA genome. (33 refs.)

78-4498 **Immunity to Antigens Associated with Primate C-Type Oncoviruses in Pregnant Women.** (Eng) Hirsch, M. S. (Massachusetts General Hosp., Harvard Medical Sch., Boston, MA, 02114); Kelly, A. P.; Chapin, D. S.; Fuller, T. C.; Black, P. H.; Kurth, R. *Science* 199(4335): 1337-1340; 1978.

Cell-mediated and humoral immune responses against antigens associated with primate C-type oncoviruses were evaluated in humans by microcytotoxicity and radioimmunoprecipitation assays. Five of six women tested sequentially during pregnancy developed selective cell-mediated reactivity against baboon endogenous virus (BEV)-infected human fibroblasts. Responsiveness peaked during the second and third trimesters and corresponded temporarily with elevated antibody levels to BEV antigens. Similar cell-mediated reactivity was not observed in nonpregnant individuals (5 women and 9 men). Selective cell-mediated reactivity directed against cells infected with the simian sarcoma virus-simian sarcoma associated virus complex (SSV-SSAV) was observed in 4/20 healthy adults (3/14 nonpregnant and 1/6 pregnant). These observations suggest that cell-mediated reactivity against primate C-type oncoviruses is occasionally detected in healthy nonpregnant adults, but that during pregnancy both cell-mediated and humoral reactivity against BEV may become selectively expressed. (21 refs)

78-4499 **Template-specific Requirements for DNA Synthesis by the Mason-Pfizer Monkey Virus DNA Polymerase: Unique Aspects.** (Eng) Marcus, S. L. (Memorial Sloan-Kettering Cancer Center, New York, NY, 10021); Sarkar, N. H.; Modak, M. J. *Biochim Biophys Acta* 519(2): 317-330; 1978.

The biochemical properties of DNA polymerase from Mason-Pfizer monkey virus (MP-MV) were investigated with respect to synthetic and natural template-primer utilization. The polymerase preferred template:primer ratios of 2.5-5:1 for optimal rates of synthesis with polycytidylic acid [poly (C)]-deoxyguanosine $_{12018}$ as template-primer. The addition of low concentrations of inorganic phosphate to the reaction mixture stimulated polyadenylic acid-directed synthesis. The chemically modified template poly(rCm) was less efficiently utilized than poly(C). Poly(2′-O-methylcytidylate), however, was the only template for which MP-MV DNA polymerase expressed a preference for $Mn^{2}+$ as divalent cation. In addition, heteropolymeric regions of rabbit globin messenger RNA and avian myeloblastosis virus (AMV) 70S RNA could be copied by the MP-MV polymerase with oligodeoxythymidylic acid, oligouridylic acid, or with endogenous primers, as in the case of AMV RNA. Although the MP-MV enzyme shared some properties with B- and C-type mammalian viral enzymes, other properties rendered it unique. The results show that, under the proper conditions, MP-MV DNA polymerase can copy natural RNA templates as efficiently as B- and C-type viral enzymes. (24 refs.)

78-4500 **Distribution and Transmission of Primate Type-C Virus.** (Eng) Kawakami, T. G. (Comparative Oncology Lab., Univ. California, Davis, CA, 95616); Sun, L.; McDowell, T. S. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 33-36; 1978.

Blood samples from 416 captive animals representing several different primate species (orangutan, chimpanzee, gorilla, macaque, woolly monkey, and marmoset) were examined for serum humoral antibody and infectious virus in an effort to determine the distribution of infectious primate C-type virus. The gibbon was the only primate that was found to be infected with a C-type virus. The virus was isolated from 9% of viremic gibbons, and humoral antibody was detected in 16% of gibbons exposed to the virus. Evidence of virus infection was found in 2/4 gibbon species studied. Contact transmission of virus was studied in pairs of gibbons in which both members were noninfected, one member was noninfected and the other was antibody-positive, one member was antibody-positive and the other was viremic, or one member was viremic and the other was noninfected. Transmission of the virus occurred only when viremic animals were involved, and virus infection occurred only when a viremic juvenile was housed with a noninfected animal of the same age. In parent-progeny transmission, virus infection occurred in offspring from viremic parent but not from noninfected or antibody-positive parents. Nucleic acid hybridization experiments using DNA from the muscle tissue of viremic animals indicated that infection in parent-progeny-infected animals occurred during the prenatal period of development or by vertical transmission. (8 refs.)

78-4501 **Identification of a Lymphotropic Simian Herpesvirus Receptor on Lymphoid Cells (Meeting Abstract).** (Eng) Nigida, S. M. (Rush-Presbyterian-St. Luke's Medical Center, Chicago, IL, 60612); Falk, L. A. *Fed Proc* 37(6): 1747; 1978. (no refs)

78-4502 **Biochemical Transformation of Mouse Cells by Herpes Simplex Virus Type 2: Enhancement by Means of Low-Level Photodynamic Treatment.** (Eng) Verwoerd, D. W. (Veterinary Res. Inst., Onderstepoort 0110, S. Africa); Rapp, F. *J Virol* 26(1): 200-202; 1978.

The effect of low-level photodynamic treatment on the transformation of thymidine kinase-deficient (TK-) 3T3-derived mouse cells (N clA cl10) by UV-irradiated herpes simplex virus type 2 (HSV-2) was determined. The inactivation of HSV-2 was first studied at high (5 μg/ml) and low (0.08 μg/ml) proflavine concentrations. Exposure of the virus to the lower concentration and 30-watt fluorescent light for 2 min had no effect on the infectivity of the virus. Studies with primary hamster embryo fibroblasts under standard conditions (1 hr incubation with 0.08 μg/ml proflavine/ml followed by exposure to light for 2 min) revealed only a 2%-5% decrease in DNA synthesis. Low-level photodynamic treatment of N clA cl10 cells at different intervals after infection also had little effect on DNA synthesis. However, treatment of TK- N clA cl10 cells under standard conditions for 2 or 5 min had an enhancing effect on the biochemical transformation of these cells to TK-positive cells. There was a two- to threefold increase in the number of transformed foci over untreated controls. With 0.08 μg/ml proflavine, the virus was not inactivated and virus and cellular DNA syntheses were inhibited only marginally. These findings suggest that photodynamically activated dyes could have a cocarcinogenic effect at very low concentrations. (4 refs)

78-4503 **Neutralizing Antibodies Against Herpes Simplex Virus Type 2 in Women with Cervicouterine Cancer.** (Spa) Ruiz-Gomez, J. (Laboratorio Nacional de Virologia, Mexico City, Mexico); Gallegos Vargas, G.; Carranza Garcia, J.; Alvarez y Munoz, T. *Ginecol Obstet Mex* 42(254): 369-375; 1977.

The presence of neutralizing antibodies against herpes simplex virus type 2 in the cervix or women with gynecological neoplasms was determined and compared to findings in women with nonneoplastic gynecologic disorders and 121 healthy controls. Neutralizing antibodies were found in 44/121 controls, in 56/93 women with cancer of the uterus and cervix ($p < 0.001$), in 7/20 patients with mild cervical dysplasia, in 8/15 patients with moderate dysplasia, in 8/15 patients with severe dysplasia, in 11/19 patients with cervicitis, in 20/63 patients with colpocervicitis, and in 25/69 patients with nongenital neoplasias. The findings indicate that there is a correlation between the incidence of virus-neutralizing antibodies and gynecological cancer and the degree of cervical dysplasia. (16 refs)

78-4504 **Induction of Cervical Carcinoma in the Mouse by Prolonged Genital Exposure to Formalin**

Inactivated Herpes Simplex Viruses Types 1 and 2 (HSV-1 and HSV-2) (Meeting Abstract). (Eng) Wentz, W. B. (Dept. Reproductive Biology, Case Western Reserve Univ. Sch. Medicine, Cleveland, OH); Reagan, J. W.; Heggie, A. D. *Pediatr Res* 12(4, part 2): 476; 1978. (no refs)

8-4505 **Binding to Chromosomes of Herpes Simplex-related Antigens in Biochemically Transformed Cells.** (Eng) Kit, S. (Div. Biochemical Virology, Baylor Coll. Medicine, Houston, TX, 77030); Kurchak, M.; Wray, W.; Dubbs, D. R. *Proc Natl Acad Sci USA* 75(7): 3288-3291; 1978.

The association of herpes simplex virus (HSV)-related antigens with chromosomes was demonstrated in human [HeLa(-BU25)] and mouse [LM(TK-)] cells biochemically transformed by UV-irradiated HSV-1. This was accomplished by using the sensitive peroxidase-antiperoxidase immunological staining technique with rabbit antisera that had high neutralizing titers against both HSV-specific thymidine kinase activity and virus infectivity. Antisera against HSV did not react with chromosomes of uninfected cells, and normal sera did not react with any of the constituents of biochemically transformed cells. Methanol/acetic acid treatment of biochemically transformed cells eliminated their nuclear staining for HSV-related antigens. In vitro binding of HSV-related antigens to chromosomes was demonstrated by incubating soluble antigens from high salt extracts of HSV-infected cells with methanol/acetic acid-fixed chromosomes of biochemically transformed or uninfected cells, followed by exposure to antiserum against HSV and peroxidase-anti peroxidase staining. There was no staining when soluble extracts from uninfected cells were substituted for those from HSV-infected cells. The results show that cells biochemically transformed and lytically infected by HSV contain antigens that, like the Epstein-Barr virus-associated nuclear antigen, bind to chromosomes in vivo and in vitro. (25 refs.)

78-4506 **The Effect of Herpesvirus Infection and 2-Deoxy-D-Glucose on Glycosphingolipids in BHK-21 Cells.** (Eng) Ray, E. K. (Dept. Physiology and Biochemistry, Medical Coll. Pennsylvania, Philadelphia, PA, 19129); Blough, H. A. *Virology* 88(1): 118-127; 1978.

The effect of herpes simplex virus (HSV) infection and 2-deoxy-D-glucose (dGlc) on the amount of radiolabeled glycosphingolipids in BHK-21 cells was studied after a 16-hr pulse with D-[3-^{3}H]serine and [1-^{14}C]palmitate. HSV infection resulted in a two- to threefold increase in the amount of labeled ceramides, ceramide monohexosides, and ceramide dihexosides and in a 50% reduction in labeled hematosides. Treatment with 10 mM dGlc increased the proportion of ceramide relative to its hexosides and reduced the total content of labeled glycolipids significantly. Glycosylation of endogenous ceramide was studied in vitro using microsomal fractions and uridine diphosphate (UDP)-[^{3}H]glucose as the sugar donor. The activity of UDP-glucose: ceramide-glucosyltransferase in cellular microsomal fractions was stimulated 30% to 80% by HSV infection and 30% to 60% by dGlc treatment. Both HSV infection and dGlc treatment increased the number or accessibility of glucose-acceptor sites. Thus, dGlc inhibits glycolipid synthesis in uninfected and HSV-infected cells by blocking the glycosylation of ceramide. The inhibition of glycolipid synthesis may play a role in virion assembly. (35 refs.)

78-4507 **Antibodies to Herpesvirus Type 1 and Type 2 among Japanese Cervical Cancer Patients.** (Eng) Ozaki, Y. (Dept. Microbiology, Shiga Univ. Medical Science, Seta, Ohtsu, Shiga-ken 520-21, Japan); Ishiguro, T.; Ohashi, M.; Sawaragi, I.; Ito, Y. *Gann* 69(1): 119-122; 1978.

The presence of antibodies to herpesvirus simplex virus types 1 and 2 (HSV-1,-2) was determined in 69 Japanese women (aged 31-72 yr) with cancer of the uterine cervix and 112 matched controls (aged 14-73 yr). The cancer patients included 7 with cervical dysplasia, 9 with carcinoma in situ, and 53 with invasive carcinoma. Antibodies to HSV-2 were found in 3 patients with dysplasia, 1 with carcinoma in situ, and 15 with invasive cancer; 17 controls also had antibodies to HSV-2. The mean antibody titer (log$_{10}$) to HSV-1 and HSV-2 was 1.89 and 1.70, respectively, in the dysplasia group, 1.95 and 1.35 in the dysplasia group, 2.12 and 1.65 in the invasive cancer group, and 2.14 and 1.67 in the control group. These findings do not support the hypothesis that there is an association between genital herpes (HSV-2) and cervical cancer. (7 refs)

78-4508 **Antibody Patterns to Herpesviruses in Kaposi's Sarcoma: II. Serological Association of American Kaposi's Sarcoma with Cytomegalovirus.** (Eng) Giraldo, G. (Memorial Sloan-Kettering Cancer Center, New York, NY, 10021); Beth, E.; Henle, W.; Henle, G.; Mike, V.; Safai, B.; Huraux, J. M.; McHardy, J.; de-The, G. *Int J Cancer* 22(2): 126-131; 1978.

The major finding of an extended serologic analysis of American and African Kaposi's sarcoma (KS) patients and appropriately matched control groups was the detection of a specific serologic association of cytomegalovirus (CMV) with American KS patients. All American KS sera contained CMV antibodies, and their geometric mean titers (GMT) were significantly higher than those in sera of melanoma patients [GMT ratio $k = 5.3$ to 7.7 by complement fixation (CF), $k = 8.9$ by indirect hemagglutination (IHA)] or in sera of age- and sex-matched healthy controls ($k = 12.6$ to 16.0

by CF, k = 12.6 by IHA). These results are similar to the data obtained previously for European KS. Although the GMT to CMV of African KS patients were similar to the GMT of the American KS groups, their significance cannot be demonstrated because of the high background of CMV infections in the control groups. Complex mechanisms are hypothesized, by analogy with the Epstein-Barr virus involvement in Burkitt's lymphoma, for a CMV involvement in the development of KS. (48 refs.)

78-4509 **Association of Cytomegalovirus (CMV) Infection with Cervical Cancer: Isolation of CMV from Cell Cultures Derived from Cervical Biopsy.** (Eng) Melnick, J. L. (Dept. Virology and Epidemiology, Baylor Coll. Medicine, Houston, TX, 77030); Lewis, R.; Wimberly, I.; Kaufman, R. H.; Adam, E. *Intervirology* 10(2): 115-119; 1978.

Cytomegalovirus (CMV) was isolated from cell cultures derived from 2/10 cervical cancer biopsy specimens of patients with invasive carcinoma. Five serial passages were necessary before extensive cytopathic changes characteristic of CMV infection appeared. All patients tested had higher titers of complement-fixing antibodies to both isolates than antibodies to the prototype AD169 strain of CMV. Six of eight patients tested also had herpesvirus type 2 antibodies. (18 refs.)

78-4510 **Epstein-Barr Virus-positive Japanese Burkitt Lymphoma.** (Eng) Miyoshi, I. (Dept. Medicine, Okayama Univ. Medical Sch., Shikatacho 2-5-1, Okayama 700, Japan); Hiraki, S.; Tsubota, T.; Uno, J.; Nakamura, K.; Ota, T.; Hikita, T.; Hayashi, K.; Kataoka, M.; Tanaka, T.; Kimura, I.; Sairenji, T.; Hinuma, Y. *Gann* 69(3): 449-450; 1978.

The first reported case of a Japanese patient with Burkitt's lymphoma whose lymphoma cells contained Epstein-Barr virus (EBV) nuclear antigen (EBNA) is described. The 29-yr-old man presented with massive ascites and large abdominal masses; cytology was suggestive of abdominal Burkitt's lymphoma. Laboratory studies indicated that 60%-70% of the ascitic lymphoma cells were EBNA-positive and that 7%-16% were EBV membrane antigen-postive. Chemotherapy resulted in regression of the ascites and abdominal masses, but 2 mo later the abdominal masses recurred with the development of meningeal leukemia. Treatment was ineffective. Autopsy revealed massive tumors involving the gastrointestinal tract, mesentery, and retroperitoneum. Histology revealed Burkitt's type undifferentiated malignant lymphoma. This case suggests that EBV may cause certain lymphomas in Japan. (10 refs.)

78-4511 **Epstein-Barr Virus-associated Antigens in Nasopharyngeal Carcinoma. Relation to Clinical Course of American Patients.** (Eng) Coates, H. L. (Mayo Clinic, 200 First St. SW, Rochester, MN, 55901); Pearson, G. R.; Neel, H. B.; Weiland, L. H. *Arch Otolaryngol* 104(8): 427-430; 1978.

The relationship between antibody titers to Epstein-Barr virus (EBV)-associated antigens and nasopharyngeal carcinoma (NPC) in American patients was quantitated with the use of 35 serum specimens. These sera were compared with 85 specimens from patients with other head and neck cancers, 80 specimens from patients with lymphoma, and 47 specimens from healthy controls. There was a definite correlation between the presence of NPC and the level of antibody titers to EBV. In particular, tests that detected antibody to early antigen and antibody to viral capsid antigen in the serum IgA fraction were highly specific for the presence of this carcinoma. Treatment that resulted in clinical remission of the disease brought about a significant decrease in these antibody titers. These findings indicate that there was a consistent and direct association between the presence of and antibody levels to EBV antigens and the presence of NPC in American patients. (20 refs.)

78-4512 **Epstein-Barr Virus Infection Following Bone-Marrow Transplantation.** (Eng) Sullivan, J. L. (Dept. Pediatrics, Univ. Massachusetts Medical Center, 55 Lake Ave. North, Worcester, MA, 01505); Wallen, W. C.; Johnson, F. L. *Int J Cancer* 22(2): 132-135; 1978.

A 12-yr-old boy with acute lymphoblastic leukemia received a bone-marrow transplant (BMT) from a matched sibling donor. Nine weeks prior to transplant, the donor experienced Epstein-Barr virus (EBV)-induced infectious mononucleosis. The bone-marrow recipient was EBV-negative at the time of transplant; however, 4 wk posttransplant, the recipient developed clinical symptoms of graft-vs-host disease (GVHD) coincident with serological evidence of acute EBV infection. In addition, a lymphoblastoid cell line positive for Epstein-Barr nuclear antigen was established for a bone-marrow sample obtained at the onset of symptoms compatible with GVHD. Sera obtained from the recipient over the ensuing 2 mo showed the appearance of antibodies to specific EBV antigens, a phenomenon consistent with a primary immune response to EBV infection. This association of acute EBV infection with symptoms of GVHD in a BMT recipient suggests a need for further investigation of the epidemiology of EBV infections in human bone-marrow transplantation and the relationship between EBV infection and GVHD. (16 refs.)

78-4513 **Heterogeneity of Epstein-Barr Virus. IV. Induction of a Specific Antigen by EBV from Two**

Transformed Marmoset Cell Lines in Ramos Cells. (Eng) Fresen, K. O. (Institut fur Virologie, Zentrum fur Hygiene, Universitat Freiburg, Hermann-Herder-Strasse 11, 78 Freiburg, W. Germany); Cho, M. S.; zur Hausen, H. *Int J Cancer* 22(2): 160-165; 1978.

nfection of cells of the Epstein-Barr virus (EBV) genome-negative human B-lymphoma Ramos line with viral solates obtained from two EBV-transformed marmoset cell ines (B95/8; Nyevu) resulted in the induction of a nuclear antigen (RAM-ag) that apparently was different from other EBV-associated antigen complexes. This antigen was revealed by indirect immunofluorescence, and it showed no deectable cross-antigenicity with Epstein-Barr nuclear antigen (EBNA) or any other known EBV-associated antigen. EBV solates from P3HR-1 cells failed to induce a similar antigen n Ramos cells, although they induced EBNA. In addition, no RAM-ag was expressed after infection of cells of another EBV genome-negative human B-lymphoma line (BJAB) with B95/8 EBV or in a series of EBV-harboring cell lines. Thus, he antigen appears to be specific for Ramos cells. It was also nduced upon infection of either B95/8 or P3HR-1-converted Ramos sublines with EBV from B95/8 cells. All human sera with RAM-ag reactivity revealed antibodies against virus capsid antigen (VCA) However, sera from patients with acute nfectious mononucleosis containing high anti-VCA antibodies did not react with RAM-ag. Apparently, seroconversion for this antigen coincides more closely with the appearance of EBNA-directed antibodies. (23 refs.)

78-4514 **Polyploidization of Epstein-Barr Virus (EBV)-carrying Lymphoma Lines Decreases the nducibility of EBV-determined Early Antigen Following P3HR-1 Virus Superinfection or Iododeoxyuridine Treatment.** (Eng) Shapiro, I. M. (Dept. Tumor Biology, Karolinska Institutet, S-104 01 Stockholm 60, Sweden); Andersson-Anvret, M.; Klein, G. *Intervirology* 10(2): 94-101; 1978.

Four tetraploid cell lines were derived from the Epstein-Barr virus (EBV)-carrying, nonproducer Burkitt's lymphoma line Raji after colcemide treatment. EBV early antigen was induced by superinfection with the P3HR-1 strain of EBV and by iododeoxyuridine treatment. Inducibility was reduced in all tetraploid lines compared with the near-diploid counterpart. The av number of EBV genome equivalents per tetraploid cell was 60-70, compared with 50 in diploid cells. This contrasts with the EBV genome amplification previously observed in somatic cell hybrids. (16 refs.)

78-4515 **Effect of Cordycepin Triphosphate on In Vitro RNA Synthesis by Picornavirus Polymerase Complex.** (Eng) Panicali, D. L. (Dept Cell and Molecular Biology, Medical College of Georgia, Augusta, GA, 30902); Nair, C. N. *J Virol* 25(1): 124-128; 1978.

The effect of cordycepin triphosphate (3′-deoxyATP; 3-dATP) on in vitro RNA synthesis by crude viral polymerase complexes isolated from HeLa cells infected with human rhinovirus type 14 or poliovirus type 2 was investigated. Polymerase complexes were also prepared from uninfected cells. In the presence of all four nucleotide triphosphates, 0.5 mM 3-dATP stimulated ^{3}H-AMP incorporation; when ATP was the sole precursor, 3-dATP caused marked stimulation of AMP incorporation not only by uninfected cell enzyme but also by the viral polymerase complexes. 3-dATP inhibited ^{3}H-guanosine monophosphate incorporation by both viral polymerase complexes. This inhibition could be reversed by adding ATP to the reaction mixture along with the inhibitor, but not by adding excess guanosine triphosphate or by adding ATP 10 min after the inhibitor. Viral products synthesized in the presence of 3-dATP lacked full-length single-stranded viral RNA. It is suggested that 3-dATP inhibits picornavirus-specific RNA synthesis by ATP competition with RNA chain termination. (17 refs.)

78-4516 **The Importance of Transcription Unit Definition.** (Eng) Darnell, J. E. (Molecular Cell Biology Dept., Rockefeller Univ., 1230 York Ave., New York, NY, 10021); Weber, J.; Goldberg, S.; Jelinek, W.; Fraser, N.; Sehgal, P. *Miami Winter Symp* 14: 197-215; 1977.

In attempts to define late adenovirus 2 (Ad2) transcripts, RNA molecules in the process of formation, "nascent" RNA, were examined. Both inside the cell and in isolated nuclei, the labeling time for RNA synthesis can be restricted to such a short period that only the termini of nascent molecules are labeled. Pulse-labeled RNA from labeled cells or from isolated nuclei labeled in vitro were separated into size classes. The RNA was then hybridized to a series of DNA fragments. The longest labeled nascent molecules were complementary to the rightmost Ad2 DNA fragment, *Eco* C, the next longest molecules hybridized to *Eco* E, and so on, back to *Sma* b. As much as 90% of the transcriptional output of any region of the Ad genome could be detected as part of a single sedimenting species. A single promoter may exist in the region around 0.2; therefore, the RNA molecules that arise from the righthand 80% of the genome will all start in the same region. RNA synthesis in a given transcription unit was decreased within the unit as an exponential function of distance from the promoter. These findings were confirmed in assays of the effect of transcription on specific regions of the Ad2 genome using HeLa cells late in Ad2 infection that were exposed to UV radiation. More than 90% of the transcription that occurs from Ad2 DNA late in infection probably begins near 0.2 and reaches to the righthand end of the genome. Since at least 20% of the RNA formed in the nucleus exits to the cytoplasm, it is concluded that the cell is able to synthesize a long RNA molecule and then modify this molecule stepwise through to messenger RNA formation. (36 refs)

78-4517 Inhibition of Exogenous RNA-dependent Protein Synthesis by a Low-Molecular-Weight RNA from Nuclear Ribonucleoprotein Particles of Adenovirus-infected HeLa Cells. (Eng) Sarma, M. H. (Div. Labs. and Res., New York State Dept. Health, Albany, NY, 12201); Beach, T. A.; Chatterjee, N. K. *Biochem Biophys Res Commun* 82(1): 384-391; 1978.

The effect of low-mol-wt RNA (I-RNA: 4S to > 5.5S) isolated from the nuclear ribonucleoprotein particles of adenovirus-infected HeLa cells on the cell-free protein synthesis directed by polyribosomal RNA from rabbit reticulocytes was studied. Increasing concentrations of I-RNA inhibited the incorporation of leucine by > 80% when protein synthesis was directed by either total or poly(A)-containing rabbit reticulocyte polyribosomal RNA. The kinetics of inhibition were similar with both preparations. Comparison of the kinetics of this inhibition with those produced by aurintricarboxylic acid indicated that I-RNA-dependent inhibition occurs predominantly at the level of chain initiation. I-RNA-dependent inhibition was relieved approx 30% by adding an excess of initiation factors, suggesting that I-RNA interacts directly with some of these factors. In a reconstituted system, I-RNA did not prevent the binding of Met-tRNAf-GTP-IF ternary complex to 40S subunits, although it did repress the formation of 80S from 40S-mRNA complex and 60S subunits. In binding assays in which authentic IF-M2A and IF-M2B were present, the inhibitor competed with messenger molecules for binding site(s) in IF-M2B. The inhibitory RNA appears to be a 5.5S RNA. (14 refs)

78-4518 Transformation of a Rat Cell Line by an Adenovirus 7 DNA Fragment. (Eng) Sekikawa, K. (Cancer Res. Inst., Sapporo Medical Coll., Sapporo 060, Japan); Shiroki, K.; Shimojo, H.; Ojima, S.; Fujinaga, K. *Virology* 88(1): 1-7; 1978.

The transforming fragment of the weakly oncogenic adenovirus 7 (Ad7, subgroup B) was studied via transfection experiments using a clonal rat embryo cell line, 3Y1. Partial digestion of Ad7 DNA by *Hin*dIII yielded fragments *Hin*dIII-B and "a"; further digestion of the latter yielded fragments *Hin*dIII-I and *Hin*dIII-J. Transfection of 3Y1 cells with Ad7 DNA and the *Hin*dIII-I-J fragment, but not with the *Hin*dIII-B fragment, yielded transformed foci and cell lines positive for adenovirus tumor antigen. Most, if not all, of the *Hin*dIII-I-J fragment persisted in the cells transformed by this fragment at a rate of 7.8 to 9.5 copies per haploid cell DNA quantity. Approx two-thirds of the viral DNA genome was present in cells transformed by Ad7 whole DNA at a rate of 3.7 to 5.7 copies per haploid quantity of cell DNA. The data indicate that the transforming gene of Ad7 is located in the *Hin*dIII-I-J fragment and is mapped at the left 8% of the Ad7 genome. (20 refs.)

78-4519 Adenovirus Type 2 Early Proteins Synthesized In Vitro and In Vivo: Identification in Infected Cells of the 38,000- to 50,000-Molecular-Weight Protein Encoded by the Left End of the Adenovirus Type 2 Genome. (Eng) Harter, M. L. (Cold Spring Harbor Lab., Cold Spring Harbor, NY, 11524); Lewis, J. B. *J Virol* 26(3): 736-749; 1978.

Sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) was used to identify the proteins synthesized early after the infection of human (HeLa) cells with adenovirus type 2 (Ad2). The major products of cell-free protein synthesis with messenger RNA (mRNA) complementary to the *Eco*RI C fragment had mol wts of 21,000 daltons (21K), 19K, 17K, and 11K; small amounts of 25K, 14K, and 13K polypeptides were also identified. With mRNA complementary to the *Eco*RI D fragment, 14K, 13K, and 15.5K polypeptides were synthesized. Polypeptides 15K and 44K to 50K were synthesized with mRNA complementary to the *Eco*RI A fragment. Six prominent proteins appeared in nuclei from Ad2-infected but not mock-infected cells: 72K, 24K, 21K, 19K, 15K, and 11K. 12K also appeared as a minor species. Cytoplasmic extracts of infected but not mock-infected cells contained 72K, 21K, 14K, and 12K polypeptides. Proteins 40K to 50K, 17K, 15.5K, and 13K were not detected in infected cells. Comparison of extracts from infected and mock-infected cells using two-dimensional isoelectric focusing/SDS-PAGE revealed six additional polypeptides with mol wts of 38K to 50K in the infected cells. A cluster of polypeptides of 38K to 50K was also synthesized in vitro using early mRNA complementary to *Eco*RI A. Partial protease digestion showed the 38K to 50K proteins synthesized in infected cells to be related in sequence to each other and to the 44K to 50K polypeptides synthesized in vitro. The results show that several closely related proteins very similar to the 38K to 50K species encoded by the left 4.5% of the Ad2 genome are synthesized in infected cells and that they accumulate in the nucleus. (34 refs.)

78-4520 Adaptation of Murine MOPC-315 Myeloma Cells to Growth In Vitro and Further Characterization of Their C-Type Viruses. (Eng) Yaniv, A. (Dept. Human Microbiology, Sackler Sch. Medicine, Tel-Aviv Univ., Tel-Aviv, Israel); Gazit, A.; Dvir, M.; Guthmann, D.; Eylan, E. *Eur J Cancer* 14(7): 771-779; 1978.

MOPC-315 myeloma cells were successfully adapted to growth in tissue culture, and the established cell line has been propagated in suspension for 2 yr (210th generation). Its tumorigenic potential was tested in BALB/c mice. Plasma cell neoplasms developed within 10 days following ip or sc injection of 10^6 cells from various generations. The viral particles released by the tumor cells during their replication in vitro were indistinguishable by nucleic acid hybridization from the C-type particles secreted into the ascitic fluid of mice bearing MOPC-

315 myelomas. The in vitro-secreted viruses, unlike those released in vivo, were unstable in sucrose and glycerol-TNE [TNE: 0.01 M Tris-HCL (pH 7.4), 0.1 M NaCl, 0.001 M EDIA] gradients. This instability was partially overcome by the addition of a reducing agent, such as dithiothreitol. The viral particles banded at densities of 1.16 and 1.19 g/ml in sucrose and glycerol gradients, respectively. Detergent treatment of MOPC-315 particles released the viral core, which had a buoyant density of 1.26 g/ml in a sucrose gradient. Two major species of RNA molecules were detected: a heavy 70S RNA and a 15S RNA; occasionally, 35S RNA molecules were also detected. The myeloma particles were infectious and capable of inducing syncytia in XC cells. (11 refs)

78-4521 **Expression of Murine C-Type Endogenous Virus by Cell Lines Derived from the 129 Mouse Teratocarcinoma.** (Fre) Emanoil-Ravicovitch, R. (Groupe de Recherches sur la Virologie des Leucemies, Unite 107 de l'I.N.S.E.R.M., Hopital Saint-Louis, 75010 Paris, France); Robert, J.; Canivet, M.; d'Auriol, L.; Peries, J. *C R Acad Sci [D] (Paris)* 28(17): 1277-1280; 1978.

Hybridization with complementary DNA (cDNA) viral probes prepared from ecotropic virus (V1) and xenotropic virus (V2) from ML/8155 infected BALB mice was performed in order to detect murine C-type viral information in differentiated and undifferentiated cell lines from the 129 mouse teratocarcinoma. Unlike the differentiated cell lines PCD1 and PCD3, the two undifferentiated cell lines, PCC4 and PCC3, were multipotential; however, only PCC3 was capable of differentiating in vitro. Other cell lines tested for hybridization with cDNA were 129 mouse embryo fibroblasts, BALB/c mouse fibroblasts, dog thymus cells, and single rhesus monkey cells. The DNA probe prepared from V1 demonstrated only slight homology with nuclear DNA in the cell lines tested. The V2 DNA probe demonstrated hybridization kinetics with the PCD1 and PCC4 lines comparable to that with the BALB/c mouse fibroblasts. Viral RNA, as demonstrated by V1, was negligible in both differentiated and undifferentiated teratocarcinoma cell lines. RNA expression using the V2 DNA probe was significantly higher in the PCC4 and PCC3 cell lines than in PCD3. When the PCC4 and PCC3 cell lines underwent differentiation in vivo, the C-type viral RNA information decreased. (6 refs)

78-4522 **Electronmicroscopic Identification of Type C Particles in Cultured Murine Neuroblastoma.** (Eng) Kataoka, S. (Dept. Anatomy, Coll. Medicine, Univ. Iowa, Iowa City, IA, 52242); Williams, T. H.; Sandquist, D.; Sahu, S. K. *Experientia* 34(7): 879-881; 1978.

Examination of monolayers of murine neuroblastoma cells treated with dexamethasone (dex) by electron microscopy revealed C-type virus particles associated with the plasma membrane or in the extracellular space. Stages ranged from budding forms to free particles. Dex increased particle incidence over that in untreated cells, but it is not known whether virus proliferation was induced by dex or if it was due to the presence of a greater number of differentiated cells. (18 refs)

78-4526 **Particles Resembling C-Type Oncornaviruses in Normal Rat Prostate.** (Eng) Zeller, N. K. (Dept. Microbiology, Univ. Maryland Dental Sch., Baltimore, MD, 21201); Bashirelahi, N.; Sydiskis, R. J. *Cancer Res* 38(9): 3104-3106; 1978.

The occurrence of viruslike particles in the ventral lobe of the prostate of a retired CD breeder rat is reported. The particles appeared to be budding from the epithelial cells into the intercellular spaces. They exhibited features morphologically similar to immature C-type particles, with an electron-lucent center and a diameter of approx 100 nanometers. Neither intracellular A-type particles nor mature C-type particles were observed. The particles appeared to be associated only with the epithelial cells lining the prostatic lumens. None of the other organs or tissues from this rat contained any virus-like particles. This is the first report of particles resembling oncornaviruses in normal rat prostatic tissue. (27 refs.)

78-4527 **Ecotropic Type C RNA Virus Expression and Its Consequences in Congenic Resistant C57BL Mice.** (Eng) Melief, C. J. (Central Lab. Netherlands Red Cross Blood Transfusion Service, P.O. Box 9190, Amsterdam, Netherlands); Vlug, A.; Barendsen, W.; De Bruyne, C.; Molenaar, J. L. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 78-83; 1978.

The expression of ecotropic C-type RNA viruses was studied in C57BL B10 and B10.A mice, which are genetically identical except for the major histocompatibility (H-2) complex. B10.A (H-2a) and B10 (H-2b) animals that received B-tropic virus through the milk of virus-positive B10.A mothers developed persistent virus infection. Genetic transmission, evidenced in part by the virus-negative status of nursing B10.A mothers, led to the heterogeneous expression of N- and B-tropic viruses in B10 and B10.A animals. This indicated that the mottled pattern for expression of ecotropic viruses in C57BL mice is controlled genetically. The H-2 complex influenced both splenic virus titers and antiviral antibody responses after milk transmission of B-tropic virus. The virus titers were higher in the B10.A animals, but the antibody titers were higher in the B10 animals. The milk-transmitted virus included lymphomas in 36% of 400 B10.A animals. (9 refs)

78-4528 **Large-Scale Isolation and Partial Purification of Type C RNA Viruses on Hydroxyapatite. Biochemical Characterization.** (Eng) Smith, R. G. (Lab. Tumor Cell Biology, NCI, Bethesda, MD, 20014); Lee, S. A. *Anal Biochem* 86(1): 252-263; 1978.

A chromatographic procedure based on the batchwise adsorption of C-type RNA viruses onto hydroxyapatite was developed for the concentration and partial purification of viruses from large volumes of tissue culture fluid (50 ml to 15 liters). The viruses obtained by this procedure have a buoyant density of 1.16 g/cm^3 and contain 70S RNA, an RNA-directed DNA polymerase (reverse transcriptase), surface glycoprotein (gp69/71), and the internal virus-specific polypeptides p10 to p15 and p27 or p30. The method was optimized for the isolation of biochemically pure virus and not for the preservation of biological activity. Th recovery of biological activity was generally below tha obtained by other small-scale methods, but it was con parable to the activity recovered by large-scale ultracei trifugation. The procedure is fast (20 to 50 liters of tissu culture fluid can be processed in 24 hr), and it uses biochemi cal reagents and equipment that are easily and economicall available. The procedure allows complete containment dur ing all stages of production, assuring sterility of the produc and safety for the worker. (33 refs)

78-4529 **C-Type Viral Immune Complexes in Leukemi and Systemic Lupus Erythematosus.** (Eng Panem, S. (Dept. Pathology, Univ. Chicago, 950 E. 59th St., Chicago, IL, 60637); Prochownik, E.; Reynolds, J.; Ordonez, N.; Slamon, D.; Kirsten, W. H. *In: Advances in Con parative Leukemia Research 1977. Proceedings of th VIIIth International Symposium on Comparative R search on Leukemia and Related Diseases, held i Amsterdam, The Netherlands on 22-26 August, 197* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New Yor Elsevier/North Holland Biomedical Press): 503 pp 50-52; 1977.

Immune response to C-type virus was investigated in patient with systemic lupus erythematosus (SLE) or hematologi neoplasms (acute leukemia, Hodgkin's disease, histiocyti lymphoma) using HEL-12 virus (isolated from human embryonic lung fibroblasts) as a probe. Virus-specific immun complexes (IC's) were found routinely in SLE kidneys an in 3/5 kidneys from the cancer patients. Circulating IgG which inhibits viral reverse transcriptases, were found frequently in the cancer patients, infrequently in normal subjects. (5 refs)

78-4530 **Activation of Endogenous Type-C Viral p30 An tigen in Chemically-induced Rat Hepatocellula Carcinomas.** (Eng) Becker, F. F. (Dept. Anatomic and Re Pathology, M. D. Anderson Hosp. and Tumor Inst., Hous ton, TX, 77030); Sherr, C. J. *Int J Cancer* 21(6): 756-76 1978.

A series of chemically induced rat primary hepatocellula carcinomas (PHC's) and several previously established trans plantable hepatocellular carcinoma (THC) lines were exam ined for expression of the major viral structural protein (p3 antigen) of endogenous rat C-type viruses. None of the si PHC's induced by exposure of male ACI rats t N-2-acetylaminofluorine expressed significantly elevated lev els of p30 antigen compared with levels in normal rat live Four PHC's gave rise to THC lines that were characterize by relatively rapid initial growth rates. For all THC lines, lo but significant levels of p30 antigen were detected after onl one transplant generation; subsequent transplants showed inreased levels. THC's derived from two PHC's were coculivated with indicator cell lines in an attempt to isolate relicating C-type virus. All indicator cell lines remained egative for reverse transcriptase activity, indicating the abence of detectable infectious C-type virus. Among six addiional chemically induced THC's, the slowly growing tumors, which tended to be more differentiated throughout their pasage in animals, failed to express elevated levels of viral antien, whereas the more rapidly growing tumors, which apeared more transformed, expressed high levels of ndogenous viral protein. The data suggest that p30 antigen xpression can be viewed as a phenotypic marker in chemically induced, rapidly growing hepatocellular malignancies of ats. (41 refs)

78-4531 **A Human Osteosarcoma Virus (Meeting Abstract).** (Fre) Prevost, J. M. (Lab. Microbiologie, nstitut J. Bordet, Universite de Bruxelles, Brussels, Belgim); Kettman, R.; Norman, C.; DeKegel, D.; Burny, A. *Bull Cancer (Paris)* 65(1): 38; 1978. (no refs)

78-4532 **Protein Metabolism in Human Skin-Muscle Embryo Cells Infected with Oncornavirus D rom J-96 Cells.** (Rus) Kishchak, V. Ya. (Central Inst. Adanced Training for Physicians, Moscow, USSR); Moisiadi, S. A.; Bektemirov, T. A. *Vopr Virusol* (4): 464-469; 1977.

To evaluate the effect of oncornavirus infection on the metabolism of cellular proteins, human skin-muscle embryo cells (HSMEC) were infected with oncornavirus D from J-96 cells. Spectra of the proteins of infected and control HSMEC cells were assessed by disk electrophoresis in polyacrylamide gel. Viral infection resulted in increased synthesis of high-mol-wt proteins and decreased synthesis of low-mol-wt proteins. Approx 90% of the proteins synthesized in the infected HSMEC were detected in the control cells and, thus, were identified as host proteins; 10% of the proteins were similar to those characteristic for J-96 cells. (16 refs.)

78-4533 **Small Virus-like Particles in Leukosis-like Syndrome Induced by Certain Antigens and Immunostimulators.** (Eng) Denner, J. (Dept. Virology, Central Inst. Cancer Res., Acad. Sciences GDR, 1115 Berlin-Buch, E. Germany); Dorfman, N. A. *Acta Biol Med Ger* 36(10): 1451-1458; 1977.

A leukosislike syndrome was induced in BALB/c mice by repeated injections of homologous or heterologous antigens plus an immunostimulator, dextran sulfate (DS) or complete Freund's adjuvant (CFA). The antigens consisted of plasma from mice with Rauscher leukemia or from healthy mice, proteins from these plasmas that were separated and bound to bovine γ-globulin, and crystalline ovalbumin. Five injections were given at 2-wk intervals. After the fifth injection, all mice that received CFA with and without antigens and DS with various antigens, but not mice that received DS alone or normal plasma alone, showed marked splenomegaly. The splenic architecture was distributed by myeloid cells of all developmental stages. The number of peroxidase-positive cells was elevated to 20%-50% of all WBC, compared with 11%-13% in normal spleen, and megakaryocytes and erythroblasts were also increased. These pathological changes were classified as leukosislike syndrome. The syndrome could be transmitted to adult BALB/c mice, mice of other strains (AKR, CC57Br, C57Bl/6), and randombred mice. Ultracentrifugation of the plasma of affected mice followed by electron microscopy of the high-speed pellets revealed the presence of viruslike particles with a diameter of 30-50 nanometers. The particles had two types of electron-dense nucleoids: ringlike or disklike, and they were surrounded by a unit membrane. Antigenic stimulation may result in activation of the virus, or an increase in certain cells may permit a virus that is present in minimal amounts to grow and multiply. (25 refs)

78-4534 **Histology of Benign Virus Induced Tumors of the Skin.** (Eng) Steigleder, G. K. (Dept. Dermatology, Univ. Cologne, Joseph-Stelzmann-Strasse 9, D-5000 Colonge 41, W. Germany). *J Cutan Pathol* 5(2): 45-52; 1978.

Histological sections of various benign, virus-induced skin tumors were studied and the findings reported. Particular attention was focused on inclusion warts, common warts, plane warts, filiform warts, focal epithelial hyperplasia, epidermodysplasia verruciformis, condylomata acuminata, and molluscum contagiosum. Electron microscopy of inclusion and other warts indicated that the viruses were present predominantly or exclusively in the nuclei of the wart cells. Transitions between common warts and condylomata acuminata have been observed, clinically and histologically, but it is not known whether these conditions are caused by the same virus. Because of its high mitosis rate, condyloma may be misdiagnosed as a carcinoma. Similarly, histological sections along the margin of a molluscum contagiosum may reveal a tumorlike proliferation similar to that of an epithelial tumor or a basal cell epithelioma. Epidermodysplasia verruciformis and condylomas, especially giant condylomas, may become carcinomatous in predisposed persons. (19 refs.)

78-4535 **Search for Oncogenic Viruses in Human Prostatic Cancer. Morphologic Studies.** (Eng)

Dmochowski, L. (Dept. Molecular Carcinogenesis and Virology, Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., Houston, TX); Ohtsuki, Y.; Seman, G.; Bowen, J. M.; Johnson, D. E. *Cancer Bull* 30(4): 112-115; 1978.

Studies attempting to establish a relationship between viruses and human prostatic carcinoma are reviewed. The observation in healthy mouse prostates of viruslike particles resembling virus found in solid tumors and leukemia of humans and of virus particles resembling those present in human breast cancer may indicate that viruses are involved in the origin of human prostatic carcinoma. (21 refs.)

78-4536 **New Virus Expressed in Cultured Human Leukaemic Myeloblasts (Letter to Editor).** (Eng) Karpas, A. (Dept. Haematological Medicine, Univ. Clinical Sch., Cambridge CB2 2QL, England). *Lancet* 2(8080): 110; 1978.

Ultrastructural examination of cultured myeloblasts from an acute myelomonocytic leukemia patient revealed numerous cytoplasmic inclusions containing 40- to 100-nanometer viruslike particles, often with an electron-lucent core and tail formation. Serological tests indicate that the virus differs from animal oncornaviruses, and the fact that antibodies could be found in some human sera supports the ultrastructural studies, which indicate that it might be a human virus. (7 refs)

78-4537 **Reduced Tumorigenicity by Addition In Vitro of Sendai Virus.** (Eng) Matsuya, Y. (Div. Microbiology, Res. Inst. Tuberculosis and Cancer, Tohoku Univ., Sendai 980, Japan); Kusano, T.; Endo, S.; Takahashi, N.; Yamane, I. *Eur J Cancer* 14(8): 837-850; 1978.

Treatment of Ehrlich ascites tumor (EAT) with Sendai virus, which has high cell-fusing activity on the viral envelope, produced polyploid variants that could grow on selective media, whereas no cell growth occurred in untreated control cultures. All of the variants isolated had more chromosomes and showed less transplantability than EAT. The banding patterns of each chromosome were analyzed. The karyotypes of the variants appeared to be more heterogeneous than EAT. Other biological properties, ie, agglutinability by concanavalin A and anchorage dependency of cell growth, proved to be unrelated to tumorigenicity. Similar variants were isolated by treating EAT with lysolecithin or polyethylene glycol, both of which are also cell-free fusion inducers. Like the variants induced by Sendai virus, they had more chromosomes and were less tumorigenic than EAT. However, the frequency of occurrence of these variants ($< 10^{-7}$) was far less than that (10^{-5}) of the variants induced by Sendai virus. It is suggested that variants preexisting in EAT begin to propagate in vitro after treatment of the tumor with fusion-inducing agents. (29 refs.)

78-4538 **Endogenous Cellular Fusion Induced In Vitro by the Visna Virus (Meeting Abstract).** (Fre) Pautrat, G. (Laboratoire de Virologie, C.H.U. Timone, 13385 Marseille Cedex 4, France); deMicco, P.; Benkoel, L.; Tamalet, J. *Bull Cancer (Paris)* 65(1): 32; 1978. (no refs)

78-4539 **Validation of Radioimmunoassays for Retrovirus.** (Eng) Charman, H. P. (NCI, Frederick, MD, 21501); Gilden, R. V. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp. 46-49; 1977.

Ongoing radioimmunoassay (RIA) studies of purified retrovirus proteins are summarized briefly, and some of the limitations of RIA are indicated. The specificity of competition RIA's is difficult to validate in crude extracts or partially purified systems. Extremes of pH, excessive protein concentrations, extremes of osmolarity, and ionic environments can interfere with antigen-antibody reactions and produce false-positive reactions. Proteolysis of labeled antigen or precipitating antibody during incubation may diminish precipitate radioactivity and apparent competition. (11 refs)

78-4540 **Site-directed Mutagenesis as a Tool in Genetics.** (Eng) Weissmann, G. (Institut fur Molekularbiologie I, Universitat Zurich, 8093 Zurich, Switzerland); Taniguchi, T.; Domingo, E.; Sabo, D.; Flavell, R. A. *Miami Winter Symp* 14: 11-36; 1977.

The infectivity of bacteriophage (Qβ) RNA was increased by substrate-controlled RNA synthesis and the introduction of a mutagenic nucleotide at a predetermined position of the viral RNA. The methodology of site-directed mutagenesis is described in detail, and its application to DNA plasmid is outlined. (27 refs)

IMMUNOLOGY

78-4541 **Similarities Among Factors that Render Macrophages Tumoricidal in Lymphokine and Interferon Preparations.** (Eng) Schultz, R. M. (Lab. RNA Tumor Viruses, NCI, NIH, Bethesda, MD, 20014); Chirigos, M. A. *Cancer Res* 38(4): 1003-1007; 1978.

Lymphokine preparations, including supernatants derived from antigen-stimulated BCG-immune spleen cell cultures and normal (BALB/c x DBA/2)F_1 spleen cells incubated with insoluble concanavalin A (Con A), were compared with partially purified L-cell interferon for the ability to render resting macrophages nonspecifically tumoricidal in vitro. Significant activation of macrophages by lymphokine preparations occurred at concentrations as low as 0.5% and 0.25% of the assay mixture for antigen-stimulated and Con A-induced lymphokine, respectively. These end point concentrations were each determined to contain 0.3 unit of interferon/ml. Supernatants obtained from unstimulated normal spleen cells, Con A-treated nu/nu spleen cells, or BCG-immune spleen cells in the absence of sensitizing antigen did not enhance macrophage tumoricidal function and lacked interferon. Activation by L-cell interferon required at least 1 unit/ml. The macrophage activating factors contained in lymphokine and interferon preparations were stable at pH 2 and at 56 C, but they were destroyed when heated at 80 C for 30 min and they were inactivated by trypsin. (20 refs)

78-4542 **Alterations in Bone Marrow and Thymus Lymphocytes in Virus-inoculated, Inbred, Preleukemic AKR/J Mice: Brief Communication.** (Eng) Hays, E. F. (Lab. Nuclear Medicine and Radiation Biology, Univ. California at Los Angeles, 900 Veteran Ave., Los Angeles, CA, 90024); Haskett, D. R.; Kaspersky, C. J.; Craddock, C. G. *J Natl Cancer Inst* 60(4): 905-909; 1978.

The thymuses and bone marrows of 5- to 6-wk-old AKR/J mice superinfected with Gross murine leukemia virus (AKR-V) were compared with those of normal aged-matched controls (AKR-N). The AKR-V mice had marrow lymphopenia, a reduction of thymus wt and cellularity, and an increase in monocyte-granulocyte progenitor cells. The number of totipotent hematopoietic stem cells did not differ in the two groups of mice. The age-related changes in the marrow and thymus lymphocytes of AKR-V and AKR-N mice were studied by comparing 5- and 8-wk-old animals. In AKR-V mice, the normal age-related fall in marrow lymphocytes was blunted. This was due to a lesser decrease of T cells and null lymphocytes and an increase in immunoglobulin-bearing lymphocytes. The changes in thymus wt and cellularity between 5 and 8 wk in the AKR-V mice reflected the actual malignant transformation in the thymus. Alterations in marrow and thymus cellularity occurring before the appearance of overt malignant lymphoma were considered to be preleukemic changes. (12 refs)

78-4543 **Lymphopoietic Action of Vitamin A in Tumor-Bearing Mice (Meeting Abstract).** (Eng) Seifter, E. (Albert Einstein Coll. Medicine, Bronx, New York, NY, 10461); Barbul, A.; Levenson, S. M.; Rettura, G. *Fed Proc* 37(3): 335; 1978. (no refs)

78-4544 **Glutathione S-Transferase in Human Lymphoid Cell Lines and Fractionated Peripheral Leucocytes.** (Eng) Kaplowitz, N. (Medical and Res. Services, Veterans Admin. Wadsworth Hosp. Center, Los Angeles, CA, 90073); Spina, C.; Graham, M.; Kuhlenkamp, J. *Biochem J* 169(3): 465-470; 1978.

Glutathione S-transferase activity was identified in the cytosol from human lymphoid cell lines and peripheral WBC (polymorphonuclear-WBC/monocyte and small-lymphocyte fractions) and compared with that of human liver enzyme. The closely similar elution volumes in gel filtration and substrate (1-chloro-2,4-dinitrobenzene) and inhibitory (probenecid) kinetics indicate that the liver, WBC, and lymphoid cell transferases are closely related. The interaction of reduced glutathione and 1-chloro-2,4-dinitrobenzene occurred in intact lymphoid cell culture, was linear with time and quantity of cells, and had kinetics similar to those of the enzyme reaction catalyzed by cytosol. Peripheral WBC and B- and T-lymphoid cell lines can be added, therefore, to the list of cell types in which glutathione S-transferases and aryl hydrocarbon hydroxylase coexist. To evaluate cancer risk, consideration must be given not only to the activation of carcinogens by aryl hydrocarbon hydroxylase but also to the inactivation of these carcinogenic products by glutathione S-transferase. (27 refs)

78-4545 **Immunological Abnormalities in Children with Acute Leukemia.** (Jpn) Goya, N. (Dept. Pediatrics, Faculty Medicine, Kyushu Univ., Higashi-ku, Fukuoka 812, Japan); Miyazaki, S. *Acta Haematol Jpn* 40(6): 1042-1048; 1977.

Humoral and cellular immunity and neutrophil bactericidal activity were evaluated in 30 children with acute lymphoblastic leukemia (ALL) and 12 with acute myeloblastic leukemia (AML). Compared with controls, IgG was lower in ALL and higher in AML patients. No significant variation in IgA or IgM was found. The patients differed significantly from each other and from the controls in their reactions to all antigens tested, with the reactions of the AML patients being more depressed than those of the ALL patients. The DNCB test was also suppressed. Study of the lymphoblast surface markers revealed that 1/17 ALL patients was T-ALL and the others were null cell ALL. Blasts with C3b receptors were found in 1/10 AML patients. Serial studies of circulating T and B lymphocytes in ALL children showed a marked fall in the number of T cells in patients in remission. After cranial irradiation, there was a significant decline in B cells. Impaired lymphocyte transformation by stimulation with PHA was detected in both patient groups. In some cases, inhibition of transformation was observed when lymphocyte cultures contained sera from children with acute leukemia. No significant relationship between histocompatibility antigens and leukemia was found. Neutrophil function was almost normal in acute leukemia in remission. The values of CH50, C3, and C4 were also within the normal range. Of the 352 cases of primary immunodeficiencies registered in Japan over a 10-yr period, 8 patients developed malignancies, only one of which was acute leukemia. (25 refs)

78-4546 **Lymphocyte Responses to Phytohaemagglutinin in Patients with Asbestosis and Pleural Mesothelioma.** (Eng) Haslam, P. L. (Dept. Medicine, Cardiothoracic Inst., Brompton Hosp., London SW3, England); Lukoszek, A.; Merchant, J. A.; Turner-Warwick, M. *Clin Exp Immunol* 31(2): 178-188; 1978.

The association between depressed cellular immunity and asbestos-associated malignancy was investigated by comparing the lymphocyte responses of 28 asbestosis patients with associated pulmonary fibrosis, 1 patient with asbestosis and lung cancer, 10 patients with pleural mesothelioma (8 with a history of asbestos exposure), and 36 nonasbestos-exposed controls to phytohemagglutinin (PHA). Quantitative impairment of lymphocyte responses was noted in 6/28 asbestosis patients. The impairment tended to occur in patients with fairly severe fibrosis, comparatively short duration of exposure to asbestos dust, and increased serum immunoglobulin (Ig) levels. The one patient with asbestosis and bronchial carcinoma also had depressed lymphocyte responses to PHA. However, 8/10 patients with asbestos-associated pleural mesothelioma without lung fibrosis showed no evidence of impaired cellular immunity, either by in vitro testing with PHA or by in vivo delayed hypersensitivity skin testing. In this group also, patients with impaired PHA responses had increased serum Ig levels. These findings suggest that there is a relationship between defective T-cell function and the fibrotic response in asbestosis, but that this finding is not common to all types of asbestos-associated malignancy. 78-4547 **Macrophage Activation for Tumor Cytotoxi
ty: Increased Lymphokine Responsiveness
Peritoneal Macrophages During Acute Inflammation.** (E
Ruco, L. P. (Immunopathology Section, Lab. Immunobio
gy, US Dept. Health, Education, and Welfare, NCI, N
Bethesda, MD, 20014); Meltzer, M. S. *J Immunol* 120(
1054-1062; 1978.

The responses of peritoneal macrophages from resident (
and inflammatory (I) populations to lymphokine (LK) a
vation were compared and analyzed. The macrophages w
collected from untreated C3H/HeN mice and from m
treated ip 1 day previously with fetal calf serum or 5 d
previously with latex beads, 3% thioglycollate, or a 2
starch suspension. Equal macrophage concentrations fr
each group of mice were cultured for 2-3 hr. Adherent I
were incubated in dilutions of LK supernatant (from purif
protein derivative of tuberculin-stimulated BCG-immu
spleen cell cultures) for 4 hr, the cultures were washed, a
^{3}H-thymidine-labeled cells from tumor 1023
methylcholanthrene-induced) were added to the monolaye
Tumor cytotoxicity by LK-activated I macrophages v
about 10 times greater than that by equal numbers of L
treated R cells. Comparisons of the time course of activati
and of the LK dose response showed that the increased
sponsiveness of the I cells was due to quantitative chang
The numbers of responsive I cells were increased 5-10 tin
with inflammation. These changes coincided with simi
changes in the numbers of peroxidase-positive (PP) mac
phages. Thus, the increased LK responsiveness of I cells
pended on the influx of young PP mononuclear phagocy
rather than the stimulation of R macrophages. This conc
was supported by the finding that whole-body x-irradiati
reduced the numbers of PP and of LK-responsive mac
phages in I- and R-cell populations. The LK-responsive p
cursor for the activated tumoricidal macrophage during b
steady-state and acute inflammatory conditions was t
newly formed blood-derived mononuclear phagocyte. T
tenfold increase in the number of LK responsive mac
phages in the peritoneal exudate over R-cell populations
flected a similar increase in macrophage turnover induced
inflammation. (38 refs)

78-4548 **Effect of Inoculation with Neuraminidase-tre
ed Tumor Cells on Macrophage Cytotoxicity
Vitro.** (Eng) Alley, C. D. (Dept. Anatomy, Medical C
Virginia, Virginia Commonwealth Univ., Richmond, V
23298); Snodgrass, M. J. *Cancer Res* 38(8): 2332-2338; 19

Adherent peritoneal macrophages (PM) and macrophag
isolated from tumor tissue of C57BL/6J x DBA/2J F_1 mi
inoculated with tumor cells treated with *Vibrio choler*
neuraminidase (VCN) and mitomycin C were studied f
their cytotoxic effect on established tumor cell monolay
by time-lapse cinematography. The two murine pulmona
tumors studied were the spontaneous Lewis Lung tumor a

3-methylcholanthrene-induced squamous cell carcinoma. Tumor cells incubated alone, with PM from untreated mice, or with macrophages isolated from tumor tissue of untreated or treated mice grew to confluence by 24 hr of coincubation and displayed no detrimental change by 96 hr. Cytotoxic PM were isolated from tumor-bearing mice that had received an sc inoculation of tumor cells treated with both VCN and mitomycin C and from tumor-free animals (1) inoculated ip with tumor cells treated simultaneously with VCN and mitomycin C or (2) given tumor cells treated with mitomycin C alone. PM from mice inoculated within 3 days of isolation with treated tumor cells killed cultures of the identical tumor by 36 hr, but they did not kill cultures of another tumor until 48 hr of coincubation. If PM were isolated 18 days following the final inoculation of treated tumor cells, they were cytotoxic (at 36 hr) to cells of that tumor only. PM from mice treated with BCG or BCG cell walls killed cultured tumor cells by 48 hr. It is concluded that specifically cytotoxic macrophages kill tumor cells by 36 hr, but nonspecifically cytotoxic macrophages do not kill until 48 hr of coincubation. (42 refs)

78-4549 **Defective Macrophage Immunity in Newborn Rabbits with Fibroma Virus-induced Tumors.** (Eng) Tompkins, W. A. (Center Zoonoses and Comparative Medicine, Coll. Veterinary Medicine, Univ. Illinois, Urbana, IL, 61801); RamaRao, G. V. *J Reticuloendothel Soc* 23(2): 161-166; 1978.

Macrophage immunity was investigated in young adult (3- to 4-mo-old) and newborn (2-day-old) rabbits inoculated with 2.5 x 10^5 plaque-forming units (PFU) of the Patuxent strain of fibroma virus id and sc, respectively. Cultured peritoneal macrophages collected from the rabbits 10 days after fibroma virus inoculation failed to show infectious virus. Vaccinia virus replicated in cultured macrophages from both normal adult and newborn rabbits, resulting in an increase in titer of 2.1 log 10 and 2.4 log 10 PFU/ml, respectively. However, vaccinia virus failed to increase in titer in macrophages from adult tumor-bearing rabbits. It did increase by 2.0 log 10 PFU/ml in macrophages from tumor-bearing newborns. Adult rabbits expressed macrophage immunity to vaccinia between 9 and 21 days after infection. Before and after this time, the macrophages supported vaccinia replication and behaved like those from normal rabbits. In contrast, macrophages from newborn tumor-bearing rabbits had no immunity by day 13 and only partial immunity before 21 days. Max macrophage immunity occurred between days 21 and 41, after which they returned to normal. (8 refs)

78-4550 **Teratocarcinoma Cell Variants Rejected by Syngeneic Mice: Protection of Mice Immunized with These Variants Against Other Variants and Against the Original Malignant Cell Line.** (Eng) Boon, T. (Cellular Genetics Unit, International Inst. Cellular and Molecular Pathology, Avenue Hippocrate, 74, B-1200 Brussels, Belgium); Van Pel, A. *Proc Natl Acad Sci USA* 75(3): 1519-1523; 1978.

The antigenic specificities of nontumorigenic (tum-) teratocarcinoma (TC) cell variants were investigated. The variants, which were obtained by treatment of a malignant TC cell line with N-methyl-N′-nitro-N-nitrosoguanidine, induce a radioresistant immune memory in syngeneic 129/Sv mice. Three weeks after immunization with 2 x 10^6 living tum- cells, the mice were given 600 rads of gamma radiation and then challenged with cells from the same clone or one of three other clones. For a given challenging clone (1 x 10^6 or 2 x 10^6 cells), immunization with a different clone conferred some protection (cross-protection), but this protection was invariably weaker than that conferred by immunization with the same variant (self-protection). Mice inoculated with 3 x 10^6 tum- cells were partially protected against challenge with 5 x 10^5 living tum+ cells, and this protection was not abolished by irradiation. In contrast, tum+ cells killed by irradiation did not elicit a rejection response. These results indicate that each tum- variant carries at least one specific transplantation antigen that is not present on the original TC line or most other variants. However, one or more common antigenic specificities are probably shared by all the tum- variants and the tum+ cells. (16 refs)

78-4551 **Genetic Dissection of the Control of Normal Differentiation in Myeloid Leukemic Cells.** (Eng) Lotem, J. (Dept. Genetics, Weizmann Inst. Science, Rehovot, Israel); Sachs, L. *Proc Natl Acad Sci USA* 74(12): 5554-5558; 1977.

Controls that regulate the induction of normal differentiation in myeloid leukemic cells were investigated using mutants that differ in the timing and degree of inducibility of differentiation-associated properties by two different inducers, the normal regulatory protein MGI and a steroid inducer (SI), dexamethasone. The sequence of differentiation was the induction of C3 and Fc rosettes, C3 and Fc immune phagocytosis (IP), synthesis and secretion of lysozyme, and formation of mature macrophages and granulocytes. Mutant clones of myeloid leukemic cells were isolated with differences in the time of induction of C3 and Fc rosettes and C3 and Fc IP (in which lysozyme was induced without going through Fc or C3 IP) and with differences in inducibility by MGI to mature macrophages or granulocytes. Only 1/5 MGI-D- clones (could not be induced by MGI for any of the properties being studied) gave rise to MGI^+D^+ mutants (clones that could be induced by MGI for differentiation-associated markers, including mature cells). The ability to obtain mutants from this clone was associated with its special chromosome constitution. Dexamethasone could induce in MGI^+D^+ clones differentiation to macrophages but not to granulocytes. Differentiation by dexamethasone in different clones occurred either with or without induction of Fc rosettes and Fc IP, and induction of C3 rosettes was not always associated with induction of C3 IP. The results indicate that there are separate controls for the induction of C3 rosettes, Fc rosettes, C3 IP, Fc IP, lysozyme, mature macrophages, and mature granulocytes. Differences in inducibility of these properties by MGI and SI support the suggestion that MGI and SI have different cellular induction sites. (35 refs.)

78-4552 **Immunologic Characterization of Hairy Cell Leukemias in Continuous Culture.** (Eng) Saxon, A. (Dept. Medicine, Div. Clinical Immunology and Allergy, Univ. California Los Angeles Sch. Medicine, Los Angeles, CA, 90024); Stevens, R. H.; Quan, S. G.; Golde, D. W. *J Immunol* 120(3): 777-782; 1978.

The immunobiologic characteristics of three continuous cell lines established from patients with hairy cell leukemia were investigated. Two of these lines were of B-cell origin, and they were established from peripheral blood samples obtained during the leukemic phase of the disease. The third was of T-cell origin and was established from spleen cells obtained at splenectomy. All lines continued to produce tartrate-resistant acid phosphatase. The B-cell lines carried Fc and C receptors, had surface and internal immunoglobulin, and did not form spontaneous sheep RBC rosettes. One of these lines has remained relatively constant in the amount of IgM produced total protein, while the other has switched immunoglobulin production from IgG to IgM. The T-cell line formed spontaneous sheep RBC rosettes and did not carry Fc or C receptors; the rosette-forming cells contained tartrate-resistant acid phosphatase. They did not possess surface or internal immunoglobulin and did not synthesize immunoglobulin in vitro. Since these hairy cell leukemia cells retain their immunobiologic properties in culture, they can be used to study this disease. (25 refs)

78-4553 **Isolation and Partial Characterization of an Antibody Enhancing Factor from Leukaemic Owl Monkey Cell Cultures.** (Eng) MacDonald, A. B. (Dept. Microbiology, Harvard Univ. Sch. Public Health, Boston, MA, 02115); Fraser, C. E.; Rubin, A. S. *Immunology* 34(1): 137-147; 1978.

The propagation of lymphoid cells from leukemic owl monkeys (*Aotus trivirgatus*) in culture, the release of a soluble factor that amplifies antibody synthesis from these cells, and the partial characterization of this mediator are described. Peripheral lymphocytes from monkeys inoculated with *Herpesvirus saimiri* and grown in culture were predominantly T cells. The supernatants from these cultures contained a factor that enhanced the antibody response of murine B cells to sheep RBC. The greatest degree of augmentation was obtained when active supernatants were added to assay cultures at 1:100 final dilution. The nonspecific stimulatory capacity at this dilution was higher than any previously reported for
similar supernatant activities recovered from appropriatel
stimulated murine or human lymphoid lines. The factor wa
found to be a protein with a mol wt of approx 40,000, an
it was not significantly affected by DNase or RNase. Trea
ment of human peripheral WBC with the factor did not pro
duce any mitogenic activity. (20 refs)

78-4554 **Lysis of Oncornaviruses by Human Serum. Is
lation of the Viral Complement (C1) Recept
and Identification as p15E.** (Eng) Bartholomew, R. M
(Dept. Molecular Immunology, Res. Inst. Scripps Clinic, L
Jolla, CA, 92037); Esser, A. F.; Muller-Eberhard, H. J. *J Ex
Med* 147(3): 844-853; 1978.

The capacity of Moloney leukemia virus to activate huma
complement was investigated. The virus activated both th
classical and alternative pathways of human complemen
about 500,000 virions were required to detect activation
the classical pathway, but 5,000 times as many virions we
needed to initiate the alternative pathway. Thus in this sy
tem, only the former pathway is of biological significanc
Disruption of the virions with Triton X-100 destroyed the
ability to initiate the alternative pathway without affectin
their ability to activate the classical pathway. Following u
tracentrifugation of the disrupted virus, the active compone
was recovered and isolated. The activity was found to resid
in a methionine-containing protein with an isoelectric poi
of 7.5 and a mol wt of 15,000 daltons. The purified prote
interacted strongly with C1q and efficiently activated C
RNase and lipolytic enzymes had no effect on the isolat
protein, but incubation with trypsin abrogated its activit
Enzymatic digestion studies indicated that the active prote
is a viral membrane protein. It is concluded that the compl
ment receptor of Moloney leukemia virus is the surface pr
tein p15E. (22 refs)

78-4555 **Immunogenetic Determinants of Familial Acut
Lymphocytic Leukemia.** (Eng) Blattner, W. A
(3C-07 Landow Building, NCI, NIH, Bethesda, MD, 20014)
Naiman, J. L.; Mann, D. L.; Wimer, R. S.; Dean, J. H.
Fraumeni, J. F. *Ann Intern Med* 89(2): 173-176; 1978.

Acute lymphocytic leukemia developed almost simultaneous
ly (within 3 wk) in two adolescent brothers, and anothe
brother and both parents had rheumatoid arthritis. Laborato
ry studies uncovered no evidence for an underlying im
munodeficiency state in the family. Immunogenetic evalua
tion showed the leukemic siblings to be histocompatibilit
antigen- and mixed leukocyte culture-identical and homozy
gous for a recessively inherited locus dictating the presenc
of antigens on the surface of B cells. These Ia antigens, a
detected by sera from mothers of leukemic children, appeare
to be mapped within the major histocompatibility region
They may be a human analog to murine immune-respons
antigens associated with susceptibility to leukemia. (23 refs.

8-4556 **HLA Antigens and Haplotypes in Acute Leukemia.** (Eng) Albert, E. D. (Tissue Typing Lab.,
inderpoliklinik der Universitat, Pettenkoferstrasse 8a, 8
unich 2, W. Germany); Nisperos, B.; Thomas, E. D. *Leuk*
es 1(4): 261-269; 1977.

he histocompatibility (HLA) antigen and haplotype fre-
uencies were determined in 198 patients with acute lympho-
lastic leukemia (ALL) and 179 patients with acute myeloge-
ous leukemia (AML) to see if there is an association between
ILA and leukemia. The findings were compared with those
f a control population of 1,070 American Caucasians. Only
ILA-A2 and A9 in patients with ALL showed an increase
ver that expected. Genotype testing indicated an increase
the gene frequencies of HLA-A2 and A9 corresponding
an increase in phenotypic expression. The gene and hap-
otype frequencies in AML were essentially normal. A study
f the patients for HLA homozygosity indicated that the fre-
uency of HLA-A homozygotes in ALL was lower than that
xpected; the frequency of HLA-A homozygotes in AML and
ILA-B homozygotes in both diseases did not differ from that
xpected. Furthermore, there was no significant excess of
amilies sharing an HLA-A,B haplotype in either disease.
egregation analysis revealed a significant predominance of
ILA-A2 in ALL patients but normal results in healthy sib-
ings. Studies of the frequency of HLA antigens in relation
o the elapsed time between diagnosis and typing indicated
hat patients with the highest frequency of HLA-A2 and A9
lso had the longest time span between diagnosis and typing.

8-4557 **Resistance to Syngeneic Lymphoma Cells as a Result of Immunization with Chemically Modi-**
ied Allogeneic Lymphoma Cells in Mice. (Eng) Gillette, R.
V. (Basic Science Unit, Cancer Center Hawaii, Univ. Hawaii
t Manoa, 1997 East-West Road, Honolulu, HI, 96822); Ber-
inger, D. C.; Wunderlich, D. A. *J Natl Cancer Inst* 60(6):
427-1432; 1978.

The effect of immunization of mice with trinitrophenyl
TNP)-derivatized allogeneic lymphoma cells on the develop-
nent of a syngeneic lymphoma was determined. This immu-
ization resulted in the development of significant immunity
o poorly immunogenic syngeneic lymphoma cells. Neither
TNP-treated nor x-irradiated syngeneic lymphoma cells were
mmunogenic under similar conditions. Immunization with
ntreated allogeneic lymphoma cells produced only minimal
evels of resistance to challenge with syngeneic lymphoma
ells. Immunization with allogeneic TNP-derivatized lymph
ode and thymus cells also did not confer any resistance,
ndicating that the immunity was carried exclusively on the
ransformed lymphocytes. The immunity was transferred to
onimmune inbred BALB/c and A/J mice by spleen cells
rom immune donors. When immune spleen cell-lymphoma
nixtures were injected sc at a ratio of 1,000:1, nonimmune
nice were completely protected. Immunization with
TNP-derivatized allogeneic lymphoma cells resulted in resistance to inocula of viable syngeneic tumor cells 100 times greater than the tumorigenic dose. Induction of immunity to syngeneic lymphoma cells required that the immunizing cells be histoincompatible at the major *H-2* locus and possess tumor-specific antigen(s). Max immune sensitivity was observed only after chemical modification of the immunizing allogeneic lymphoma cells. (40 refs)

78-4558 **Malignant Lymphoma Arising in Angioimmunoblastic Lymphadenopathy.** (Eng) Nathwani, B. N. (Dept. Anatomic Pathology, City Hope Natl. Medical Center, 1500 E. Duarte Road, Duarte, CA, 91010); Rappaport, H.; Moran, E. M.; Pangalis, G. A.; Kim, H. *Cancer* 41(2): 578-606; 1978.

Histopathologic and clinical data are presented for 48 patients with angioimmunoblastic lymphadenopathy (AILD) and 36 with AILD + immunoblastic lymphoma (IL) in the diagnostic biopsy. In the first group, progression to IL was observed in 8/23 patients with AILD in whom follow-up biopsies or autopsy was performed. Multiple clusters or islands of compactly arranged large lymphoid cells constituted the initial histologic evidence of IL. Subsequent tissue examination revealed progression of the disease in the form of diffuse replacement of lymph nodes by the neoplastic cellular proliferation. There were no significant differences in the past history, clinical, or laboratory findings between the AILD patients and those with AILD + IL. These two groups differed greatly, however, with respect to complete remission following prednisone and/or chemotherapy (63% for AILD vs 26% for AILD + IL); median survival (35 mo vs 6 mo); incidence of malignant lymphoma at autopsy (20% vs 82%); and the finding of extranodal malignant lymphoma at autopsy (10% vs 64%). In the AILD group, the median survival of patients who had complete remission after prednisone was significantly longer than that of patients who had partial or no remissions; the same was true for patients given chemotherapy. In the AILD + IL group, a similar difference in the median survival was observed in patients treated with chemotherapy, but not in those treated with prednisone. (61 refs)

78-4559 **Prolonged Lifespan and High Incidence of Neoplasms in NZB/NZW Mice Treated with Hydrocortisone Sodium Succinate.** (Eng) Walker, S. E. (R4633 Kresge I, 1405 East Ann St., Ann Arbor, MI, 48109); Anver, M. R.; Schechter, S. L.; Bole, G. G. *Kidney Int* 14(2): 151-157; 1978.

The effectiveness of prolonged hydrocortisone sodium succinate (HCSS) therapy (3.3 or 10 mg/kg/day, sc) in preventing early death from renal disease was studied in young female hybrid New Zealand Black/New Zealand White mice. Control mice were given sc saline. Long-term therapy with either

HCSS dose effectively prevented renal disease and prolonged the lives of the mice. Fifty-six percent of the animals given the lower dose and 76% of those given the higher dose developed neoplasms. The most common neoplasms were sarcomas, which appeared in aged animals and tended to involve the reproductive tract. Lymphoreticular malignancies developed in 6/22 animals with tumors. The data support the conclusion that neoplasia is an important consequence of long-term treatment of autoimmune disease in hybrid New Zealand mice. (25 refs.)

78-4560 **Ultrastructural Studies on Hydantoin Induced Lymphomas in Mice.** (Eng) Bedoya, V. (Univ. Antioquia Medical Sch., Medellin, Colombia, South America); Krueger, G. R. *Z Krebsforsch* 91(2): 195-204; 1978.

Ultrastructural studies were done on cells from original tumors and from short term cultures of mouse thymic lymphomas experimentally induced by chronic exposure to diphenyl-hydantoin. The tumors appeared in mouse strains with low (C57Bl) and high (SJL/J) susceptibility to spontaneous lymphoma development and were not observed in a resistant strain (C3Hf). Thymic lymphoma development was usually preceded by increasing lymphoreticular atrophy followed by progressive reticulohistiocytic hyperplasia, and subsequently spread to other tissues. Morphologically the tumor was characterized as a lymphoblastic lymphoma. Abnormal cell changes in the original tumors and cultured cells, and the presence of murine C-type particles in the cultured cells but not in the original tumors, are discussed in relation to the disturbance of the immune system and the lymphoma enhancement produced by diphenyl-hydantoin. (25 refs)

78-4561 **Effects of Light In Vivo on Mouse Lymphoma Cells Pretreated In Vitro with Hematoporphyrin (Meeting Abstract).** (Eng) Coppola, A. (Downstate Medical Center, Brooklyn, NY); Viggiani, E.; Salzarulo, L.; Rasile, G. *Fed Proc* 37(3): 413; 1978. (no refs)

78-4562 **Growth Inhibition of Normal or Drug-treated Lymphoma Cells in Lethally Irradiated Mice.** (Eng) Riccardi, C. (Sch. Medicine, Inst. Pharmacology, Univ. Perugia, Perugia 06100, Italy); Fioretti, M. C.; Giampietri, A.; Puccetti, P.; Goldin, A.; Bonmassar, E. *J Natl Cancer Inst* 60(5): 1083-1090; 1978.

The growth inhibition of LSTRA and L5178Y lymphomas, which carry the *H-2d*, or 5-(3,3-dimethyl-1-triazenyl)-1H-imidazole-4-carboxamide (-DTIC)-modified lymphoma sublines was studied in lethally irradiated (850-900 rads) mice. Graded doses of lymphoma ce were injected iv into histocompatible or allogeneic mi that were either susceptible or resistant to *H-2d* bo marrow grafts according to their hematopoietic-hist compatibility (*Hh*) system. Radioresistant inhibiti of tumor (RIT) responses were determined by measu ing the extent of ^{125}I-2′-deoxyuridine uptake in t spleens and livers of recipient mice. RIT respon were detected against both parental and DTIC-treat sublines in *Hh*-resistant or *Hh*-susceptible allogen hosts. Marginal or no RIT responses against *H-* LSTRA or L5178Y lymphomas were found in inbred or h brid hosts carrying the *H-2d* haplotype. Nevertheless, we but significant responses were detected in recipients of t same genotype challenged with DTIC sublines. The resu of the experiments suggested that: (1) parental DTIC-treated lymphomas could share *Hh* antigens wi normal bone marrow cells of the strain of orig although no direct evidence was obtained in the studies; (2) leukemia cells might express tumor-associat antigens, not detectable in normal bone marrow ce that are capable of eliciting RIT responses in *Hh*-susce tible allogeneic mice; and (3) additional transplantati antigens could be expressed by DTIC sublines th elicited presumably weak RIT responses in letha irradiated histocompatible recipient hosts. (38 ref

78-4563 **Enhancement of Natural and Antibody-Depen ent Lymphocyte Cytotoxicity by Drugs Whi Inhibit Prostaglandin Production by Tumor Target Cel** (Eng) Droller, M. J. (Dept. Urology, Johns Hopkins Hos Baltimore, MD); Perlmann, P.; Schneider, M. U. *Cell I munol* 39(1): 154-164; 1978.

A ^{51}Cr release assay was used to examine the effects of pros glandin inhibitors on natural and antibody-depende cell-mediated cytotoxicity against T_{24} cells, (derived fro bladder transitional tumor, and HCV_{29} cells, derived fro normal bladder transitional epithelium but probably tra formed in tissue culture. Cells labeled with ^{51}Cr were incub ed with lymphocytes from venous blood of normal dono prostaglandin inhibitors [indomethacin (Indo: 10^{-9}-10^{6}M acetylsalicyclic acid (10^{-7}-10^{-5}M), the sodium salt of fenclo acid (10^{-7}-10^{-5}M), and 2,6-xylenol (10^{-7}-10^{-5}M), a T_{24} antiserum for 16-20 hr at 37 C. All four dru enhanced natural and antibody-dependent cell-mediat cytotoxicity against T_{24} and HCV_{29}, generally in dose-dependent manner. The presence of antiseru with or without the inhibitory agents, did not enhan ^{51}Cr-release, nor was enhancement seen when t agents were incubated with target cells in the absen of lymphocytes. Time course studies indicated that t longer the inhibitors were present during incubation, t greater the enhancement of lymphocyte cytotoxicity. The a dition of exogenous prostaglandins (10^{-8}-10^{-7}M) to the inc bation tubes prevented the Indo-induced enhancement cytotoxicity. These results support the suggestion that tum

:lls protect themselves against cytotoxic lymphocytes by ·oducing inhibitory levels of prostaglandins. (14 refs.)

8-4564 **Enhancement of Heterotransplanted Human Tumor Graft Survival in Nude Mice Treated ith Antilymphocyte Serum and in Congenitally Athym- -Asplenic (lasat) Mice.** (Eng) Gershwin, M. E. (Dept. ledicine, Sch. Medicine, Univ. California, Davis, CA, 5616); Ikeda, R. M.; Erickson, K.; Owens, R. *J Natl Cancer nst* 61(1): 245-248; 1978.

leterotransplanted human tumor graft survival was studied 1 unmanipulated and antilymphocyte serum (ALS)-treated ongenitally athymic (nude) mice and in congenitally athym- :-asplenic (lasat) mice to investigate the relationship between he immune status of nude mice and the transplantation of uman tumor lines. The 11 tumor lines used were taken from breast adenocarcinoma, bladder transitional cell carcinoma, steosarcoma, fibrosarcoma, Hodgkin's disease, malignant nelanoma, and rhabdomyosarcoma. Only 3/11 tumor lines vere successfully transplanted in unmanipulated nude mice, ompared with 5/10 tumor lines in ALS-treated nude mice nd 9/11 lines (except for the transitional cell carcinoma and habdomyosarcoma lines) in lasat mice. Moreover, the laten- y period was shorter and the minimum cell inoculum size vas lower for lasat mice than for nude or ALS-treated nude nice. In no experimental situation was there evidence of tu- nor metastasis. It is concluded that tumor grafting occurs nore readily in immunologically deprived nude mice, and it s suggested that both major immunologic and nonim- nunologic events are critical in the balance between success- ul xenografting and rejection and between local tumor pro- luction and metastases. (31 refs)

78-4565 **Growth Response in Athymic Nude Mice to Transplanted Growth Hormone-secreting Rat Pituitary Tumor Cells.** (Eng) Shin, S. (Dept. Genetics, Albert Einstein Coll. Medicine, 1300 Morris Park Ave., Bronx, NY, 10461); Brown, A. L.; Bancroft, F. C. *Endocrinology* 103(1): 223-228; 1978.

Clonal cell lines derived from a somatotropic rat pituitary umor were grafted sc into athymic nude mice, and the growth response induced in the graft carriers was examined. When at least 10^6 rat tumor cells were injected per mouse, virtually all mice developed slow-growing, nonmetastasizing umors at the injection site. In immature nude mice, the somatotropic effect of the rat growth hormone (GH) secreted by the growing tumor was clearly evident, as body wt con- inued to increase well beyond that of control litter- mates (760 g, compared with 32 g). The action of he rat GH was generalized, since even the largest mice etained apparently normal physical proportions. The slets of Langerhans in the host pancreas was especially hypertrophic, presumably due to the anti-insulin activity of GH. The rat pituitary tumor cells synthesized and secreted a protein that was precipitated by rat GH antiserum and that comigrated with authentic rat GH when analyzed by sodium dodecyl sulfate-acrylamide electrophoresis. Through serial transplantation in nude mice, the tumor cells retained their functional and tumorigenic properties. These results demonstrate that rat GH is active in the mouse and they suggest that the athymic nude mouse should be useful for the development of other xenogenic tumor lines that secrete GH. 78-4566 **Association Between Tumorigenesis and the State of the Immunocompetent System in Mice.** (Pol) Neiman, I. M. (Inst. Nutrition, Moscow, USSR); Finogenova, M. A. *Patol Fiziol Eksp Ter* (2): 26-29; 1978.

The effect of stimulation of connective tissue with antilymphocytic serum (ALS) on methylcholanthrene (MC)-induced carcinogenesis was studied in CBA x C57BL mice. ALS administration (0.05 ml, sc) 48 hr before MC injection (0.04 ml of 0.5% soln, sc) inhibited the development of MC-induced skin tumors: 22 wk after MC administration, 60% of the ALS-treated mice developed papillomas, compared with 85% of the controls. Malignant transformation of the papillomas occurred in only 16% of the ALS-treated mice, vs 36% of the controls. (17 refs)

78-4567 **A Quantitative Micro-complement Fixation Method in Studies of Human Wart Viruses.** (Eng) Hefton, J. M. (Lab. Human Tumor Virology, Memorial Sloan-Kettering Cancer Center, New York, NY 10021); Eisinger, M. *J Gen Virol* 38(1): 179-182; 1977.

Microcomplement fixation was used to detect the reactions between human hand wart virus antigens and monospecific rabbit antiserum directed against human wart virions. The antigen titers obtained from the count analysis of the microtest were constantly four to eight times higher than those obtained from a visual analysis of microtest RBC pellets. The monospecific antisera did not react with other papovaviruses such as simian virus 40, BK, or JC virus, and all reactivity could be removed by absorption with human wart virus but not with normal skin. It is concluded that the reactions were specifically between human hand wart viruses and antibodies directed against them. This test can be used to study the roles of these viruses in human neoplasia. (9 refs.)

78-4568 **Tumor Rejection Antigens in Subcellular Fractions Isolated from an Ultraviolet Light (UV) Induced Murine Skin Tumor (Meeting Abstract).** (Eng) Otterstrom, J. R. (Hershey Medical Center, Hershey, PA, 17033); Schengrund, C. L.; Bartlett, G. L. *Fed Proc* 37(6): 1562; 1978. (no refs)

78-4569 **Enhancement of Experimental Lung Metastases by Cultured B16 Melanoma Cells Treated with (±)-1,2-Bis(3,5-dioxopiperazin -1-yl)propane(ICRF-159).** (Eng) Lazo, J. S. (Dept. Pharmacology, Comprehensive Cancer Center, Yale Univ. Sch. Medicine, New Haven, CT, 06510); Ingber, D. E.; Sartorelli, A. C. *Cancer Res* 38(8): 2263-2270; 1978.

The in vitro colony-forming (CF) efficiency of exponentially growing B16 melanoma cells was significantly decreased after they were exposed to ≥ 20 μM (±)-1,2-bis(3,5-dioxopiperazin-1-yl)propane (ICRF-159). Under identical conditions, ICRF-159 significantly increased the in vivo lung CF efficiency of these cells. Thus, 24 hr after 20 μM ICRF-159, the ability of melanoma cells to form colonies in vitro was reduced by 89%, although the lung CF efficiency of these same cells was enhanced 5.5-fold after tail vein injection into syngeneic mice. The ratio of in vivo to in vitro CF efficiency of cells treated with 20 μM ICRF-159 for 24 or 48 hr was 50- to 110-fold higher than that seen with untreated cells. Mice inoculated sc with ICRF-159-treated cells developed tumors later and survived longer than mice that received untreated control cells. The increase in tumor latent period and mean survival time was consistent with a 90% decrease in cell viability observed with the in vitro CF assay. The enhanced ability of B16 cells to form lung colonies after ICRF-159 treatment appears to be due to a drug-induced change in the cells, rather than to the presence in the cell population of a mixture of dead and viable cells. Cell volume and the incorporation of precursors of glycosaminoglycans were increased after ICRF-159 treatment, and this may be responsible for the enhanced lung CF efficiency. The findings suggest that ICRF-159 may increase the ability of circulating melanoma cells to implant and grow in susceptible distant organs. Since circulating tumor cells are often found in patients with solid tumors, the metastatic potential of these cells may be enhanced by only partially effective chemotherapy. (26 refs)

78-4570 **Squamous-Cell Carcinoma of the Floor of the Mouth.** (Eng) Ballard, B. R. (Dept. Pathology, Meharry Medical Coll., 1005 18th Ave., N., Nashville, TN, 37208); Suess, G. R.; Pickren, J. W.; Greene, G. W.; Shedd, D. P. *Oral Surg* 45(4): 568-579; 1978.

The clinical and biologic behavior of squamous cell carcinoma of the floor of the mouth was studied in 100 patients (81 men and 19 women). Ninety-four were Whites and six were Blacks; the age range was 33-85 yr, with an av of 63 yr. The peak incidence in women was in the 50 to 59 yr age group; in men, there was equal frequency in each age group > 50 yr. A total of 43/89 patients diagnosed within 1 yr of the onset of symptoms had regional lymph node metastases. The 5-yr survival rate decreased from 86% to 0% as the stage of disease progressed from I to IV. Thirty-three patients developed a total of 83 other primary cancers, and 72 of these arose in the upper alimentary and respiratory tracts. The oral carcinomas were classified as follows: well-differentiated (49), well- to moderately differentiated (7), moderately differentiated (20), moderately to poorly differentiated (10), poorly differentiated (2), and unspecified (12). Fifty-eight patients were heavy smokers, 33 were heavy drinkers, 28 were both heavy smokers and heavy drinkers, and 21 were nonsmokers and nondrinkers. (48 refs)

78-4571 **Nasopharyngeal and Adjacent Neoplasms: A Clinico-pathologic and Immunologic Study.** (Eng) Uhlmann, C. (ENT Clinic and Immunopathology Labs., Pathology Inst., Univ. Cologne, Joseph-Stelzmann-Strasse 9, D-5000 Cologne 41, W. Germany); Krueger, G. R.; Sesterhenn, K.; Rose, K. G.; Ablashi, D. V.; Wustrow, F. *Arch Otorhinolaryngol (NY)* 218(3/4): 163-177; 1978.

Thirteen cases of nasopharyngeal carcinoma (NPC) and 16 cases of non-NPC tumors in the nasopharynx or in adjacent locations were investigated clinically immunologically, and pathologically. All tumors were classified according to the TNM classification, and the stage and course of the disease were correlated with tumor histology, the T- and B-cell distribution in tumor tissue and in the peripheral blood, as well as with antibody titers against Epstein-Barr virus (EBV). There was a positive correlation between decreased T and B cells in tumor tissue and decreased T cells in the peripheral blood with the extent of the tumor in both NPC and non-NPC cases, except for some lymphoepithelial carcinomas and malignant lymphomas. Elevated titers of anti EBV antibodies were observed in anaplastic carcinomas and in lymphoepithelial carcinomas type Regaud, but not in classical squamous cell carcinomas, giant follicular lymphomas, or non-NPC tumors. Although only a limited number of patients with NPC were studied, repeated serological testing allowed the conclusion that there was some correlation between antibodies to EBV early antigen and viral capsid antigen and the stage of the tumor. 78-4573 **Modification of the Immunologic Properties of the Cell Surface.** (Eng) Hakim, A. A. (Dept.

Surgery, Physiology Biophysics, Univ. Illinois Medical Center, Chicago, IL, 60680). *Immunol Commun* 7(1): 25-39; 1978.

The comparative immunologic effects of glutaraldehyde-, formalin-, 2,4,6-trinitrophenylate-, *Vibrio cholerae* neuraminidase-, iodoacetate-, heparin-, histamine-, and cyclic AMP-treated living CF_1 mouse-transplantable spontaneous mammary adenocarcinoma cells were determined in syngeneic CF_1 mice. Animals immunized with the fixed (formalinized or glutaraldehyde-fixed) neuraminidase-treated cells or the membrane of these cells rejected two challenging doses of 10^8 viable unmodified adenocarcinoma cells. Animals immunized with adenocarcinoma cells treated with neuraminidase (170 IU/5 x 10^5 cells) or with the spontaneous adenocarcinoma cell-surface-associated glycoprotein, rejected the first challenging dose but developed tumors and died on the second challenge with the viable untreated adenocarcinoma cells. Animals immunized with the adenocarcinoma cells pretreated with trinitrophenylate, glutaraldehyde, or formalin developed temporary resistance to the spontaneous mammary adenocarcinoma. Adenocarcinoma cells pretreated with NaF, iodoacetate, heparin, EDTA, colchicine, or histamine showed reduced oncogenicity and stronger resistance in mice to the development of a mammary tumor than to a smaller number (10^3) of untreated viable adenocarcinoma cells. Cells treated with cyclic AMP accelerated tumor development. (31 refs)

78-4574 **Further Studies on the Relationship Between Large Glycoprotein Molecules and Allotransplantability in the TA3 Tumor of the Mouse: Studies on Segregating TA3-Ha Hybrids.** (Eng) Codington, J. F. (Lab. Carbohydrate Res., Dept. Biological Chemistry, Massachusetts General Hosp., Boston, MA, 02114); Klein, G.; Cooper, A. G.; Lee, N.; Brown, M. C.; Jeanloz, R. W. *J Natl Cancer Inst* 60(4): 811-818; 1978.

The chemical and biological characteristics of epiglycanin were studied in six TA3-Ha/A.CA hybrid cell lines in order to obtain information on its role in antigen masking in the TA3 tumor system. The cell lines were formed by fusion of the TA3-Ha mammary carcinoma of a strain A mouse with a normal embryonic fibroblast of an A.CA mouse and then converted to the ascites form in parental strain A mice. The ability of these lines to grow in foreign mouse strains was inversely related to their ability to absorb anti-H-2a antibody. The absorptive capacities of the hybrid cell lines were intermediate between the low absorptive capacity of the non-strain-specific parent TA3-Ha ascites cell line and the much higher absorptive capacity of the strain-specific ascites line TA3-St of the same tumor. Each hybrid cell line possessed an abundance of large endogenous cell-surface glycoprotein molecules similar to epiglycanin, a glycoprotein detected at the surface of the parent TA3-Ha cell. The results suggested that the amount of epiglycaninlike material at the hybrid cell surfaces may have been directly related to the capacities of the cells to grow in foreign mouse strains and inversely related to their capacities to absorb anti-H-2a antibody. (28 refs)

78-4575 **In Vitro Studies on Splenocyte Cytotoxicity Against Syngeneic Mammary Carcinomas of Mice. 1. Reactivity of Splenocytes from Mice Bearing Mammary Tumors Against the Corresponding and Against Other Neoplasms.** (Eng) More, R. (Lautenberg Center General and Tumor Immunology, Hebrew Univ.-Hadassah Medical Sch., Jerusalem, Israel); Yron, I.; Weiss, D. W. *Isr J Med Sci* 14(1): 146-161; 1978.

As demonstrated by a terminal ^{51}Cr-labeling assay, splenocytes of BALB/c mice bearing large, progressively growing implants of the D7T4S syngeneic mammary carcinoma, which does not express the known mature mammary tumor viruses (MTV), markedly reduced the numbers of viable corresponding tumor target cells after culture in vitro. Similar cytotoxic reactivity was shown by splenocytes from BALB/c genotype animals bearing MTV-positive D14 mammary tumors. Spleen cells from normal BALB/c genotype donors exhibited only occasional cytotoxic activity against these neoplasms. Removal of glass-adherent cells from splenocyte populations from normal syngeneic mice decreased their in vitro cytotoxicity for D7T4S and D14 target cells was manifested. In contrast, removal of glass-adherent cells did not lower the cytotoxic potency of splenocytes from tumor-bearing donors. Preliminary studies were conducted on the specificity of these cytotoxic reactions. Splenocytes from mice with isografts of a plasmacytoma and of two methylcholanthrene(MC)-induced fibrosarcomas, with demonstrated cytotoxic reactivity for the corresponding tumor cells, exerted no cytotoxic effects on D7T4S targets. However, there was cross-reactivity between mammary carcinomas and a third MC-induced sarcoma. Cross-reactivity was also evident between spontaneous and transplanted MTV-positive mammary carcinomas and D7T4S. Thus, the specificity of cellular immunity against murine mammary tumors and other experimental neoplasms is highly problematic. (39 refs.)

78-4576 **Time Distributions of Recurrences of Immunogenic and Nonimmunogenic Tumors Following Local Irradiation.** (Eng) Suit, H. D. (Edwin L. Steele Lab. Radiation Biology, Dept. Radiation Medicine, Massachusetts General Hosp., Harvard Medical Sch., Boston, MA, 02114); Sedlacek, R.; Fagundes, L.; Goitein, M.; Rothman, K. J. *Radiat Res* 73(2): 251-266; 1978.

Tumor recurrences and the appearance of radiation-induced sarcoma were investigated in 314 10- to 12-wk-old C3Hf/Sed mice that received single-dose irradiation (4,000-7,100 rads at 950-975 rads/min) of the leg and thigh as treatment of an 8-mm mammary carcinoma isotransplant. The times for the transplant tumor inoculum to grow to an 8-mm tumor and the times of death due to local regrowth, distant metastasis, or induced tumor were all approx log-normally distributed. The 128 recurrences occurred 30-436 days after irradiation, mainly during the early part of this period; only 3/128 recurrences occurred >300 days postirradiation. These findings were interpreted to mean that in some cases, mice were cured of the leg tumor by radiation alone at doses of 6,500-7,100 rad. Radiation-induced sarcomas began to appear after 300 days. The time of appearance of the radiation-induced tumors was inversely related to radiation dose. Similar data for an immunogenic fibrosarcoma (induced by methylcholanthrene) indicated that recurrences appeared earlier and were more closely bunched with respect to time than the recurrences of mammary carcinoma. The time distribution of the development of radiation-induced tumors in non-tumor-bearing animals was not different from that for radiation-induced tumors in mice that had been treated for tumor. It does not appear, therefore, that the frequency of tumor induction by radiation is altered by the prior growth of a tumor in the irradiated site. (17 refs)

78-4577 **Identification of Lipids Associated with the Ability of Tumor Cells to Resist Humoral Immune Attack (Meeting Abstract).** (Eng) Schlager, S. I. (NIH, Bethesda, MD, 20014); Ohanian, S. H.; Borsos, T. *Proc Am Assoc Cancer Res* 19: 94; 1978. (no refs)

78-4578 **Suppression of Growth of Guinea Pig Line-10 Hepatocarcinoma. I. Effect of Simultaneous Administration of Tumor Cells and Antibodies from Normal Rabbits.** (Eng) Brunda, M. J. (Natl. Jewish Hosp. and Res. Center, Denver, CO, 80206); Minden, P.; Heusser, C. H.; Ferguson, H. R. *J Immunol* 120(3): 831-836; 1978.

Serum or immunoglobulins (Ig) from normal New Zealand white rabbits were mixed with the diethylnitrosamine (DEN)-induced line-10 hepatocarcinoma from strain-2 guinea pigs and injected id into normal guinea pigs to study the role of antibodies in tumor rejection. Suppression of growth of the line-10 hepatocarcinoma occurred when 10^5-10^6 cells were injected with sera or Ig. A significant number of animals were also resistant to subsequent rechallenge with tumor cells. The immunity was specific and it depended on contact of the Ig with the tumor cells and on the concentration of Ig. Repeated injections resulted in the development of immunity in 11/13 recipients. Fc receptors were not detected on line-10 cells. Antibodies reacting with line-10-unique antigens and with antigens common to line 10, DEN-induced line-1, and normal guinea pig spleen cells were found in normal rabbit sera. Injection of line-10 cells together with rabbit Ig from which antibodies reacting with line-10 antigens had been removed did not result in tumor suppression. The specific antigen(s) recognized by antibodies that suppressed the growth of the line-10 tumor in vivo was not identified. (35 refs)

78-4579 **In Vitro Measurement of Carcinogen-resistant Liver Cells During Hepatocarcinogenesis.** (Eng) Laishes, B. A. (Dept. Pathology, Univ. Toronto, Medical Sciences Bldg., Toronto, Ontario M5S 1A8, Canada); Roberts, E.; Farber, E. *Int J Cancer* 21(2): 186-193; 1978.

Hyperplastic nodules from the liver of male Fischer 344 albino rats fed a diet containing 0.02% 2-acetylaminofluorene (AAF) for 14-16 wk were transferred to primary monolayer cultures, and the proportion of nodule cells resistant to aflatoxin B_1 (AFB) was determined. Nodule and normal cell cultures were exposed to 10^{-7}-10^{-5} mole/liter AFB for 24 or 48 hr. The nodule cell cultures contained a larger number of resistant cells than cultures from normal rat liver. At all AFB concentrations, there was approx a threefold drop in the percentage of surviving nodule-derived cells; survival of normal cells decreased twentyfold. A comparatively large population of hepatocytes from nodule liver did not even respond morphologically to the AFB, and they continued to spread out on the substratum in the same way as cells in control cultures without AFB. Furthermore, some nodule cells survived exposure to AFB for up to 2 mo. Dexamethasone supplementation of the culture media increased the longevity of normal hepatocytes and increased the proportion of resistant normal cells exposed to 10^{-6} and 10^{-5} mole/liter AFB, but did not significantly increase the size of the resistant nodule cell population. It is not known whether the resistance to cytotoxicity in vitro is the result of reduced levels of certain components of the chemical-carcinogen activation system, reduced uptake of the carcinogen, or increased amounts of intracellular molecules that bind carcinogens. (35 refs)

78-4580 **Immune Response of the Draining and Distal Lymph Nodes During the Progressive Growth of a Chemically-induced Transplantable Rat Hepatoma.** (Eng) Jones, J. A. (Cancer Res. Campaign Labs., Univ. Nottingham, Univ. Park, Nottingham, NG7 2RD, England); Robinson, G.; Rees, R. C.; Baldwin, R. W. *Int J Cancer* 21(2): 171-178; 1978.

The immune response in lymph nodes draining the site of a 4-dimethylaminoazobenzene-induced hepatoma (D192A) implanted im in male W/Not rats was investigated. Cell-mediated cytotoxicity against hepatoma D192A and 15-day rat embryo cell targets was detected in cells from the draining lumbar node 4 days after tumor implantation; this persisted up to 2 wk of tumor growth and decreased during week 3. The reactivity of tumor bearer cervical lymph node cells increased with progressive tumor growth. The lymph node anergy observed in the cytotoxicity tests correlated with the paracortical (T-dependent) response, which decreased toward the end of 3 wk. The B-dependent cortex showed active lymphocyte follicles during the second week, and plasma cell production continued until the experiment was terminated. These changes occurred with progressive increase in lymph node mass. Serum antibody specific for the developing tumor was detected after day 20. (33 refs)

78-4581 **On the Mechanism of Reduction of Antiblastomogenic Resistance in Nephrogenic Hypertension.** (Rus) Litvitsky, P. F. (Dept. Pathophysiology, I. M. Sechenov First Medical Inst., Moscow, USSR); Kogan, A. Kh. *Patol Fiziol Eksp Ter* (1): 62-63; 1978.

The reduction of antiblastomogenic resistance due to nephrogenic hypertension was studied in random-bred rats. Nephrogenic hypertension was simulated by left nephrectomy with subsequent (10-14 days later) stenosing of the contralateral renal artery. On days 13-14 of hypertension, animals received one of the following: a paraffin disk implant containing 2 mg of benzo(a)pyrene (BP) or a transplant of carcinoma PC-1, sarcoma 45, Walker carcinoma 256, or Zajdela hepatoma cells. The functional state of the immune system was measured by the carcinolytic activity of the serum (CAS) and the number of lymphocytes and plasmacytes in the spleen specimens. The amount of 11-oxycorticosteroid (11- OCS) in the blood plasma was also assessed. The CAS decreased from 3.78 in intact (control) animals to 3.06 on day 28 of hypertension and 2.79 on day 100 of hypertension. The decrease was even more pronounced in animals with BP-induced tumors (0.63) and animals with carcinoma PC-1 (0.67). Rats with hypertension had a slightly decreased number of splenic lymphocytes: 321.6 on day 28 of hypertension, compared with 359.0 in controls, 273.6 in rats with hypertension + BP-induced tumors, and 280.0 in rats with hypertension + sarcoma 45. The blood plasma content of 11-OCS was increased in rats with hypertension and in those with hypertension + tumors. (22 refs)

78-4582 **Abrogation of Tumor Rejection by Trypan Blue.** (Eng) Kreider, J. W. (Dept. Pathology, Coll. Medicine, Coll. Medicine, Pennsylvania State Univ., Hershey, PA, 17033); Bartlett, G. L.; DeFreitas, E. *Cancer Res* 38(4): 1036-1040; 1978.

A determination was made of the effects of chronic trypan blue treatments on three animal tumor models in which strong, tumor-specific rejection immunity developed: a UV-induced cutaneous mouse tumor (UVT-2051), a diethylnitrosamine-induced line 1 guinea pig hepatoma, and a line 10 guinea pig hepatoma. UVT-2051 tumor fragments were implanted sc in the mice, and trypan blue was administered ip at a dose of 4 mg on day -1 and again 3 hr before tumor grafts; 1 mg 2x/wk was given thereafter. With line 1 cells, 3 x 10^6 cells were injected sc; with line 10, 1 x 10^5 cells were injected id in the flank, and a vaccine of irradiated cells and BCG was administered simultaneously in the other flank. For the two tumor models, guinea pigs received 30 mg/kg trypan blue sc on day 0 and 2x/wk thereafter, or 100 mg/kg on day 0 and a maintenance dose of 15 mg/kg 2x/wk thereafter, respectively. Trypan blue treatment prevented tumor-specific rejection in all three systems, but the secondary immune reactions to line 10 challenges were abolished. The mechanism by which tumor-specific rejection was inhibited is not known. (25 refs)

78-4583 **Hepatitis B Antigen in Black Patients with Hepatocellular Carcinoma: Correlation Between Orcein Stained Liver Sections and Serology.** (Eng) Cohen, C. (Dept. Anatomic Pathology, Hershey Medical Center, Hershey, PA 17033); Berson, S. D.; Geddes, E. W. *Cancer* 41(1): 245-249; 1978.

Formalin-fixed, paraffin-embedded liver and tumor tissue from 50 black mineworkers with hepatocellular carcinoma (HCC) were examined by orcein stain for the presence of cytoplasmic hepatitis B surface antigen (HBsAG). In 16/18 cases, HBsAG-positive liver tissue correlated with positive serum HBAg. The two false-positive serum HBAg results were obtained by immunodiffusion (ID), immunoelectrophoresis (IEP), and complement fixation (CF). Of the 32 HBsAG-negative cases, 14 had a negative serum HBAg upon ID, IEP, and CF, but a positive serum HBAg upon radioimmunoassay or hemagglutination. Six other negative orcein results appeared to be due to a sampling error. Although orcein staining of tumor cells was positive in three patients with serum HBAg, the staining reaction was equivocal. Provided the limitations of the technique are realized, orcein staining of liver tissue may be useful in retrospective studies of the prevalence of HBAg in HCC patients. (28 refs.)

78-4584 **Association Between HLA Antigens and Gastro-Intestinal Neoplasia (Meeting Abstract).** (Eng) Gennari, L. (Istituto Nazionale Tumorii, Universidad di Milano, Milan, Italy); Spinelli, P.; Pellegris, G.; Illeni, M. T.; Garotta, G. *Digestion* 16(3): 240; 1977. (no refs)

78-4585 **Quantitative Analysis of Immunogenic Activity of SV40 and of Tumor Cells Induced by This Virus.** (Rus) Klyuchareva, T. E. (Cancer Res. Center, USSR

Acad. Medical Sciences, Moscow, USSR). *Biull Eksp Biol Med* 86(8): 223-225; 1978.

Investigations of specific antitumor immunity induced in Syrian hamsters by oncogenic simian virus 40 (SV40) or by cells of SV40-induced tumors in Syrian hamsters indicated a direct correlation between the level of specific antitumor resistance and the immunizing virus or tumor cell dose. The minimal resistance-inducing dose of wild-type SV40 virus was 10 times higher than that of the temperature-sensitive mutant of this virus (tsA-30). The minimal resistance-inducing dose of irradiated tumor cells was about 9 x 10^5 cells; a 10-fold increase in this dose significantly increased the specific antitumor immunity level. (8 refs)

78-4586 **Immunity Against MOPC 104E Plasmacytoma: Effects of Tumor Size and Time Post Therapy on In Vivo Tumor Immunity.** (Eng) Lubet, R. A. (Dept. Biochemistry, Univ. Texas Health Science Center at Dallas, 5323 Harry Hines Blvd., Dallas, TX, 75235); Carlson, D. E. *J Natl Cancer Inst* 60(5): 1107-1111; 1978.

Ten- to 12-wk-old BALB/c mice with palpable sc MOPC 104E plasmacytomas (6-15 x 10^7 cells) were treated with cyclophosphamide (CP: 10 or 250 mg/kg ip) and, at various intervals, rechallenged with different doses of viable tumor cells, and the effects of tumor size and time posttherapy (PT) on in vivo tumor immunity were determined. When CP-treated ("cured") animals were given a secondary challenge of 3 x 10^3-2 x 10^6 tumor cells 22, 45, 120 days PT, they had a considerable increased ability to reject the challenge, and the av time of tumor appearance (in any "immune" animals that did permit tumor growth) was delayed. All low-CP-dose mice showed similar degrees of tumor immunity: a TD_{50} between 200,000 and 800,000 viable cells and a similar period of tumor latency (15.3 vs 10 days in controls with 200,000 cells). Similar tumor immunity levels were found in all high-CP-dose mice, but they were lower than those of the low-dose animals. Tumor latency was also delayed in these mice (20.8 vs 17.2 days with 1.25 x 10^4 cells). Thus, tumor immunity remained constant for at least 4 mo PT. A second group of animals was treated with 10 mg/kg CP 4, 11, or 20 days after tumor cell injection and then rechallenged with various numbers of viable tumor cells 30 days PT. These three subgroups rejected 6, 60, or 400 times as many tumor cells, respectively, as did controls. Thus, animals cured of large tumors and, by implication, exposed to greater amounts of tumor antigens showed greater residual tumor immunity than animals cured of relatively small tumors. (25 refs)

78-4587 **Cell-Surface Major Glycoprotein of BALB/c Mouse Plasmacytoma 58-8 Cells.** (Eng) Tokuyama, H. (Dept. Immunology Res., Roswell Park Memorial Inst., 666 Elm St., Buffalo, NY, 14263); Migita, S. *J Natl Cancer Inst* 61(1): 203-208; 1978.

Alterations of cell-surface components of BALB/c mouse plasmacytoma 58-8 cells during successive ip transplantations in syngeneic mice were studied by sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE). By SDS-PAGE and PAS staining, all 58-8 cells were found to have a common, unique, PAS-positive (PAS+) major membrane component (MMC) with a mol wt of about 170,000 daltons. The amount of this component increased with increasing transplants. The MMC appeared to be a major constituent of cell-surface membranes, since it was removed from cells by trypsinization and since its level in the crude membranes was 22-fold higher than that in the whole cell. An analysis of the SDS-PAGE patterns of surface-iodinated 58-8 cells revealed a prominent surface membrane component with the same mol wt (170,000 daltons) as that of the PAS+ MMC; the amount of this component also increased with increasing transplants. The PAS+ MMC and the iodinated major component appeared identical, as both were sensitive to tryptic digestion and the extraction percentage of the PAS+ MMC (29.8%) and the iodinated major component (28%) by 1 M urea was similar. The real mol wt of the PAS+ glycoprotein was estimated to be 120,000 daltons by SDS-PAGE. The PAS+ major glycoprotein contained a high amount of sialic acid residues. The sialoglycoprotein on the cell surface of 58-8 cells appeared to be the masking material that made the 58-8 cells unreactive with antibodies directed to their tumor-associated antigens or to the histocompatibility H-2 antigen. (15 refs)

78-4588 **Serologic Identification of Multiple Tumor-associated Antigens on Murine Sarcomas.** (Eng) Parker, G. A. (Surgery Branch, NCI, NIH, Public Health Service, U.S Dept. Health, Education, and Welfare, Bethesda, MD 20014); Rosenberg, S. A. *J Natl Cancer Inst* 58(5): 1303-1309; 1977.

Humoral immune responses to two transplanted chemically induced (3-methylcholanthrene) murine sarcomas (MCA-2 and MCA-3) were studied in C57BL/6N mice. These tumors were immunogenic, as evidenced by tumor amputation and rechallenge experiments, and they did not cross-react in in vivo challenge experiments. In a complement-dependent microcytotoxicity assay, antibodies to both MCA-2 and MCA-3 were detected in the sera of animals bearing MCA-3 and of those which had tumors removed. The sera of animals hyperimmunized to MCA-3 (MCA-3HI) were also cytotoxic with high titers to both MCA-2 and MCA-3 (50% cytotoxicity titers of 1:80 and 1:320, respectively). Sequential absorptions of sera from animals bearing MCA-3 and MCA-3HI sera with fresh MCA-2 cells completely removed the activity against MCA-2 but not the reactivity to MCA-3. Sequential absorptions with fresh MCA-3 cells produced stepwise reductions of activity against both tumors, but absorption with normal cells produced no loss of activity against either tumor. Thus, both specific and cross-reactive antigens were expressed on the surfaces of MCA-3 cells. Only the specific tumor antigen appeared to be involved in in vivo protection against tumor challenge. (28 refs.)

78-4589 **Failure of Neuraminidase Treatment to Influence Tumorigenicity or Immunogenicity of Syngeneically Transplanted Rat Tumour Cells.** (Eng) Pimm, M. V. (Cancer Res. Campaign Labs., Univ. Nottingham, Nottingham NG7 2RD, England); Cook, A. J.; Baldwin, R. W. *Eur J Cancer* 14(8): 869-878; 1978.

Vibrio cholerae neuraminidase (VCN) and *Clostridium perfringens* neuraminidase were examined for their ability to reduce the tumorigenicity of a range of seven different transplanted rat tumors. The enzymes released 0.2 to 1.2 micromoles of sialic acid/10^9 cells, comparable to levels reported by others. However, in no case did treatment of tumor cells with either enzyme consistently reduce in vivo tumorigenicity over and above that caused by the enzymes' buffer soln. Moreover, with a strongly immunogenic 3-methylcholanthrene-induced sarcoma, VCN treatment of cells did not improve their efficiency for active specific immunotherapy, and enzyme treatment of cells of an N-hydroxy-2-acetylaminofluorene-induced mammary carcinoma, nonimmunogenic by conventional criteria, did not render them immunogenic. These studies fail to confirm the reduced tumorigenicity of neuraminidase-treated cells or their increased immunogenicity. (36 refs.)

78-4590 **Lymphocytotoxic Autoantibodies Eluted from In Vivo Propagating Sarcoma Cells of Mice: Brief Communication.** (Eng) Ran, M. (Dept. Microbiology, George S. Wise Center Life Sciences, Tel-Aviv Univ., Tel-Aviv, Israel); Yaakubowicz, M.; Witz, I. P. *J Natl Cancer Inst* 60(6): 1509-1513; 1978.

Eluates of SEYF-a cells (from a polyoma virus-induced sarcoma grown in A.BY mice) containing cytotoxic anti-SEYF-a antibodies were found to mediate the complement-dependent cytotoxicity of normal lymph node cells. Some lymphocytotoxicity was also mediated by the sera of tumor-bearing mice, but the pattern of cytotoxicity was different from that exhibited by the tumor eluates. The titer of lymphocytotoxic antibodies in the serum was lower than the titer of anti-SEYF-a antibodies, but eluates exhibited similar titers toward both target cells. These findings indicate that the tumor cells selectively absorbed the lymphocytotoxic antibodies from the serum. Tumor eluates also had cytotoxic activity against thymocytes, splenocytes, and bone marrow cells. The strain distribution of sensitive thymocytes to the antibodies present in the eluates indicated that Thy 1 was not involved. Unfractionated eluates as well as IgG fractions isolated from eluates were active in mediating cytotoxicity. (24 refs)

78-4591 **Solubilized Tumour-Associated Antigens of Methylcholanthrene-induced Mouse Sarcomas. Comparative Studies by In Vitro Sensitization of Lymph-Node Cells, Macrophage Electrophoretic Mobility Assay and Transplantation Tests.** (Eng) Bubenik, J. (Inst. Molecular Genetics, Czechoslovak Acad. Sciences, 16610 Prague 6, Czechoslovakia); Indrova, M.; Nemeckova, S.; Malkovsky, M.; Von Broen, B.; Palek, V.; Anderlikova, J. *Int J Cancer* 21(3): 348-355; 1978.

The immunologic potential and antigenic specificity of solubilized tumor-associated antigens (TAA) extracted from methylcholanthrene-induced sarcomas in C57BL10/ScSn mice were examined by in vitro sensitization of lymph node cells (LNC), macrophage electrophoretic mobility (MEM) assay, and transplantation tests. The solubilized TAA elicited both primary and secondary immune responses in vivo, as judged from induction of transplantation resistance. The resistance to transplantation of the corresponding sarcoma cells was tumor-specific, partial, and weaker than that induced by immunization with irradiated tumor tissue. Treatment of mice with solubilized TAA prior to immunization with irradiated tumor tissue inhibited the induction of transplantation resistance by irradiated tumor cells. The interaction of the solubilized TAA preparations in vitro, either with LNC from animals immunized against the corresponding tumor or with LNC from tumor-bearing animals, gave rise to a macrophage-slowing factor detectable by the MEM test. TAA detected by the MEM assay in extracts of individual sarcomas were non-cross-reacting and individually distinct. Individual specificity of TAA present in the sarcomas was also demonstrated in vitro by sensitization of normal syngeneic LNC on monolayers of irradiated sarcoma cells, followed by detection of the generated cytotoxic LNC in a cytotoxicity assay. Although sensitization of LNC on layers of irradiated sarcoma cells gave rise to lymphocytes cytotoxic for cells of the sensitizing tumor, sensitization of LNC with solubilized TAA isolated from the same sarcoma gave negative results. (35 refs)

78-4592 **Tumor Inhibition by Effector Cells Cultured from Progressing Sarcomas.** (Eng) Berczi, I. (Dept. Immunology, Faculty Medicine, Univ. Manitoba, Winnipeg R3E OW3, Manitoba, Canada); Sehon, A. H. *Immunol Commun* 6(6): 617-632; 1977.

The effect of cytotoxic lymphoid cells emerging in primary cultures of an antigenic methylcholanthrene-induced sarcoma in inbred Sewall-Wright strain 13 guinea pigs was investigated on tumor growth in vivo. The growth of lethal tumor inocula was inhibited or the tumor cells were completely rejected in normal syngeneic recipients treated sc with 5 x 10^5 effector cells mixed with the tumor cells. A higher dose (2.5 x 10^6) of killer cells did not affect tumor growth significantly in normal recipients. Significant tumor inhibition was observed in x-irradiated recipients given 2.2 x 10^6 effector cells locally, although rejection did not occur with high frequency. Local treatment of irradiated recipients with 5 x 10^5 effector cells did not influence tumor growth. Systemic treatment of normal and irradiated recipients with effector cells had little effect at any dose, although tumor inocula were occasionally rejected. Sonication of the effector cells prior to administration inhibited their tumor-suppressing effect. Animals that rejected the first tumor inoculum were immune to a second lethal dose. These findings illustrate the complexity of the tumor-host interaction. (25 refs)

78-4593 **In Vitro and In Vivo Expression of Original and Foreign H-2 Antigens and of the Tumor-associated Transplantation Antigen of a Murine Fibrosarcoma.** (Eng) Carbone, G. (Div. Experimental Oncology A, Istituto Nazionale per lo Studio e la Cura dei Tumori, Via G. Venezian 1, 20133 Milan, Italy); Invernizzi, G.; Meschini, A.; Parmiani, G. *Int J Cancer* 21(1): 85-93; 1978.

The expression of original and foreign histocompatibility (H-2) antigens and tumor-associated transplantation antigen on the C-1 3-methylcholanthrene-induced BALB/c fibrosarcoma was investigated. The binding of C57BL/6J or C3Hf anti-BALB/c sera or that of monospecific alloantisera to H-2d specificities on plated C-1 cells indicated that the H-2d antigen expression was lower or undetectable on the in vitro tumor. The low expression of H-2d antigens on in vitro C-1 cells was confirmed by absorption experiments that allowed a direct comparison of in vivo and vitro cells. In these experiments, in vitro C-1 cells were unable to absorb the cytotoxicity of C57BL/6J antiBALB/c serum. H-2k antigens found on C-1 were examined using BALB/c anti-C3Hf, anti-AKR, anti-C57BL/6J polyspecific sera and also monospecific alloantisera against H-2k antigens. The expression of H-2k antigens was significantly lower in the in vitro than in the in vivo tumor, with antigen 5 being undetectable in the cultured cells. Allogeneic and syngeneic sera raised against in vitro or in vivo C-1 cells were tested on either BALB/c or C3Hf normal lymph node cells by the complement-dependent cytotoxicity assay. A significantly higher titer of cytotoxic antibodies to H-2d and to H-2k was obtained in the allogeneic and syngeneic sera, respectively, following immunization with the in vivo C-1 cells, compared with sera raised against the in vitro line. In vivo and in vitro C-1 cells had the same tumor-associated transplantation antigen, and its expression was not significantly reduced on cultured cells. (29 refs.)

78-4594 **Immunoprevention of Cancer in Experimental Animals: Strategies that Might be Useful in Prevention of Cancer in Man.** (Eng) Huebner, R. J. (NCI, Bethesda, MD); Gilden, R.; Fish, D.; Djurickovic, D.; Toni, R.; Stephenson, J.; Hill, P.; Trimmer, R.; Whitmore, C.; Rhim, J. *In: Carcinogens: Identification and Mechanisms of Action. Proceedings of the Thirty-First Annual Symposium on Fundamental Cancer Research Held at Houston, Texas, 1-3 March 1978.* University of Texas System Cancer Center, M. D. 78-4595 **Genetic Studies of Autoimmunity and Retrovirus Expression in Crosses of New Zealand Black Mice. I. Xenotropic Virus.** (Eng) Datta, S. K. (Hematology Service, New England Medical Center Hosp., Boston, MA, 02111); Manny, N.; Andrzejewski, C.; Andre-Schwartz, J.; Schwartz, R. S. *J Exp Med* 147(3): 854-871; 1978.

The role of xenotropic virus in the development of autoimmune disease was investigated in the progeny of crosses between New Zealand Black (NZB) and SWR mice. [(NZB x SWR)F_1 x SWR] mice and the F_2 progeny segregated into three phenotypes: high-virus, low-virus, and virus-negative; F_1 and (F_1 x NZB) progeny were always high virus. Autoantibodies, immune deposit nephritis, and lymphomas developed in the progeny of these crosses. The virological phenotype of the animal could be dissociated from the presence of either autoantibodies or nephritis: mice that expressed virus titers as high as the NZB parent failed to develop signs of autoimmunization, even up to 24 mo of age. However, some (F_1 x SWR) and F_2 mice that expressed low titers of virus developed autoimmune disease. Furthermore, a proportion of virus-negative mice produced autoantibodies and had typical immune deposit nephritis. No viral antigens could be detected in the renal lesions of such virus-negative animals. By contrast with the dissociation between expression of virus and occurrence of nephritis, the presence of antibodies to DNA correlated with the development of renal lesions. Thus, genes determining the expression of infectious xenotropic virus in NZB mice segregate independently from those involved in the autoimmune disease of these animals. (46 refs)

78-4596 **Genetic Studies of Autoimmunity and Retrovirus Expression in Crosses of New Zealand Black Mice. II. The Viral Envelope Glycoprotein gp70.** (Eng) Datta, S. K. (Hematology Service, New England Medical Center Hosp., Boston, MA, 02111); McConahey, P. J.; Manny, N.; Theofilopoulos, A. N.; Dixon, F. J.; Schwartz, R. S. *J Exp Med* 147(3): 872-881; 1978.

The viral envelope glycoprotein gp70 was measured in the serum of crosses of new Zealand Black (NZB) x SWR mice, and the levels were analyzed in relation to the expression of infectious xenotropic virus, presence of autoantibodies, and development of glomerulonephritis and lymphomas. The progeny of the crosses had serum gp70 values that segregated to NZB-like and SWR-like levels. A complex mechanism determined the inheritance of NZB-like serum gp70 levels. The factors determining the expression of this retroviral protein were independent of the genes (*Nzv-1* and *Nzv-2*) that determined the expression of infectious xenotropic virus. Autoimmune disease, including immune deposit nephritis, could be dissociated from the degree of expression of serum gp70. However, the presence of circulating immune complexes and anti-DNA antibody did correlate with the development of nephritis in these crosses. A significant correlation was found between high-grade expression of serum gp70 and the presence of lymphomas in these mice. (16 refs)

78-4597 **Antibody Stimulation of Benzo(a)pyrene Carcinogenesis.** (Eng) Curtis, G. L. (Univ. Nebraska Medical Center, Omaha, NB, 68105); Ryan, W. L.; Stenback, F. *Cancer Lett* 4(4): 223-228; 1978.

The possibility that chemical carcinogens induce a humoral antibody that plays an active role in carcinogenesis was investigated using female Swiss mice immunized with benzo(a)pyrene (BP). Antibody to BP was induced by inoculating the mice three times with BP conjugated to horse serum albumin (HSA) [1.6 (μmol) BP to 2.5 x 10^{-2} μmol protein/ip injection]. Three weeks after the final injection, 10 mg BP was applied to the shaved skin of these mice; mice that had been immunized with HSA only, and nonimmunized mice. The mice that had been immunized with BP-HSA had significantly more tumors than the nonimmunized mice. The slight increase in the HSA-immunized group could have ben due to the Freund's complete adjuvant injected with the HSA. A total of 2.5 mg BP was then incubated with diluted or undiluted rabbit anti-BP sera or normal rabbit sera and then injected into mice. Mice that received BP incubated with normal sera had three tumors regardless of whether the sera was diluted or undiluted. Mice that received BP incubated with rabbit anti-BP sera undiluted and diluted 1:5 had significantly more tumors than any group in which BP was incubated with normal rabbit sera. These results suggest that the immune response to carcinogens is an important component of carcinogenesis. (19 refs)

78-4598 **Antibody and Complement Modulation of Tumor Cell Growth In Vitro and In Vivo.** (Eng) Shearer, W. T. (Dept. Pediatrics, Washington Univ. Sch. Medicine, St. Louis, MO, 63110); Parker, C. W. *Fed Proc* 37(10): 2385-2389; 1978.

The results of recent experiments on antibody (ab) and complement (C) modulation of tumor cell growth in vitro and in vivo are reviewed. The transformed L cell line was covalently substituted with trinitrophenyl (TNP) groups and exposed to microgram amounts of highly purified rabbit and anti-TNP ab for various times. The ab specifically stimulated nucleoside uptake in the cells. Low doses of heated rabbit antiserum raised to membrane antigens on L cells also stimulated nucleoside incorporation into L cells, but the response was more marked than that seen in the TNP system. The anti-L cell ab also stimulated in vitro DNA synthesis and cell growth in the L cells. High concentrations of ab inhibited these processes. C activated through C3 augmented the cytostimulatory (CS) effect of low concentrations of ab; C activated through C9 augmented the cytoinhibitory effects of ab. A very early effect of CS concentrations of ab was activation of membrane carrier transport systems, as determined by measurements of $^{45}Ca^{2}+$ uptake in L cells treated with various doses of anti-L cell ab and C. This activation only took place when the cells were also stimulated to grow. Growth of L cells in tissue culture in the continuous presence of a CS concentration of ab selected for a variant cell line (LC_1) that was less responsive to ab, probably because of a blocking effect of increased amounts of sialic acid. LC_1 cells contained twice as much total cellular sialic acid residues as L cells. In vivo experiments documented that the same ab could modulate L-cell growth in T-cell-depleted C3H mice, depending on whether a low or high concentration of ab was given passively. It is concluded, however, that these effects of ab and C on tumor cell growth do not necessarily operate in autochthonous tumor systems, especially in human malignancies. (18 refs.)

78-4599 **True Plasma Corticosterone Levels of Mice in Cancer/Stress Studies (Meeting Abstract).** (Eng) Spackman, D. H. (Pacific Northwest Res. Foundation, Seattle, WA, 98104); Riley, V.; Bloom, J. *Proc Am Assoc Cancer Res* 19: 57; 1978. (no refs)

78-4600 **Antibody Response of Mice to Chemically Induced Tumors.** (Eng) Brown, J. P. (Div. Tumor Immunology, Fred Hutchinson Cancer Res. Center, Seattle, WA, 98104); Klitzman, J. M.; Hellstrom, I.; Nowinski, R. C.; Hellstrom, K. E. *Proc Natl Acad Sci USA* 75(2): 955-958; 1978.

The humoral immune response of BALB/c mice to 3-methylcholanthrene (3-MC)-induced sarcomas was examined to determine whether antibodies were produced against the unique tumor-specific transplantation antigens (TSTA) or against antigens of murine leukemia virus (MuLV). The 3-MC-induced sarcomas varied with respect to their expression of endogenous MuLV. Immunization of syngeneic mice with MuLV-free tumors failed to elicit antibodies against TSTA or MuLV antigens. Immunization with MuLV-producing tumors, however, induced a vigorous antibody response to the envelope proteins of MuLV. Antibodies formed against the MuLV-producing tumors cross-reacted in serological assays with antigens present on other MuLV-producing tumors, but they did not react with antigens on MuLV-free tumors. These data imply that the mechanisms leading to the rejection of chemically induced sarcomas are primarily cellular. (26 refs)

78-4601 **Antitumor Antibody Synthesis In Vitro Induced in Mouse Spleen Cells by Xenogeneic Immune RNA.** (Eng) Kern, D. H. (Dept. Surgery, Harbor General Hosp., Torrance, CA 90509); Pilch, Y. H. *J Natl Cancer Inst* 60(3): 599-603; 1978.

When incubated with xenogeneic immune RNA (I-RNA), globulin preparations from normal, nonimmune C3H mouse spleen cells contained antibody activity against 3-methylcholanthrene- or benzo(a)pyrene-induced fibrosarcomas. Globulins from spleen cells incubated with I-RNA extracted from the lymphoid organs of guinea pigs that had been immunized with either of the two cross-reacting chemically induced C3H mouse sarcomas reacted against target cells of both tumors, but not against target cells of a spontaneously syngeneic osteosarcoma. Globulins from spleen cells incubated with I-RNA from guinea pigs immunized with osteosarcoma cells or cells from a spontaneous C3H mouse mammary tumor reacted with either of the two chemically induced sarcomas, but globulins from spleen cells incubated with antiosteosarcoma I-RNA did not react with osteosarcoma target cells. Globulins from spleen cells incubated with I-RNA extracted from guinea pigs immunized with complete Freund's adjuvant only or with a pool of normal C3H mouse tissues exhibited no reactivity against any of the three target cells tested. The antitumor antibodies synthesized by xenogeneic I-RNA were apparently specific for the particular tumor used to immunize the I-RNA donor. (23 refs.)

78-4602 **Relationship Between the Production of Antibodies Against the Common Enterobacterial Antigen and Carcinogenesis Suppression.** (Rus) Montsevichyute-Eringene, E. V. (Scientific Res. Inst. Oncology, Vilnius, USSR). *Patol Fiziol Eksp Ter* (1): 58-61; 1978.

The formation of antibodies against a common enterobacterial antigen during carcinogenesis and the effect of these antibodies on the growth of induced tumors were studied in random-bred albino rats. Two series of the experiments were performed. In the first series, rats received a single injection of benzo(a)pyrene (BP) or 3-methylcholanthrene (3-MC) (both, 5 mg in 0.4 ml of peach oil, sc). Seven days later, the animals were inoculated with an extract of *Bacillus faecalis alcaligenes* (Bfa), and serum antibodies were assessed by double diffusion. Antibodies against Bfa were detected in 55.7% of the rats exposed to carcinogens, compared with 20.8% of the control (untreated) animals. In the second series, 25 rats with antibodies against Bfa and 25 rats without the antibodies were inoculated with BP (5 mg, sc). The former showed a significant inhibition of tumorigenesis: the av tumor wt and latent period in rats with antibodies against Bfa were 35.5 g and 159 days, compared with 90.9 g and 138 days in rats lacking the antibodies. (17 refs)

78-4603 **In Vivo Modulation of Thymus-Leukemia Antigens on Mouse Leukemia Cells and Thymocytes: Retention of Modulating Antibody on the Cell Surface.** (Eng) Jacobson, J. B. (Donald S. Walker Lab., Sloan-Kettering Inst. Cancer Res., 145 Boston Post Road, Rye, NY, 10580); Galuska, S.; Stackpole, C. W. *J Natl Cancer Inst* 61(3): 819-825; 1978.

Murine thymus-leukemia (TL) antigen modulation was investigated in vivo to determine whether modulation within the animal results in a total loss of modulating antibody and modulated antigens from the cell surface. Inoculation of RADA1, ASL1, and ERLD murine leukemia cells into the peritoneal cavities of (C57BL/6J x A/TL-)F$_1$ mice hyperimmunized against TL cell-surface antigens rendered most cells insensitive to in vitro lysis by guinea pig complement, even in the presence of TL antiserum. Thymocytes of A/J mice were similarly modulated by passive injection of TL antiserum. In both cases, the retention of some modulating antibody on the surfaces of most cells modulated in vivo for 1-27 days was indicated by: (1) acquisition of sensitivity of modulated cells to lysis by absorbed rabbit complement; (2) positive immunofluorescence reactions for mouse IgG on the surfaces of modulated cells; and (3) release of cytolytically active TL antibody from cells into the circulation of unimmunized mice following transfer of modulated cells. Reversal of modulation of RADA1 cells was complete in some experiments within 24 hr after transfer to unimmunized mice, by which time all indications of cell-bound TL antibody were lost. These findings indicate that even long-term modulation of TL antigenicity in vivo does not result in a complete loss of modulating antibody (presumably attached to TL antigens) from the cell surface. (14 refs.)

78-4604 **Comparison of the Mode of Immunopotentiating Action of BCG and Wax D. II. Effect on the Methylcholanthrene Carcinogenesis.** (Eng) Ishibashi, T. (Res. Inst. Diseases Chest, Faculty Medicine, Kyushu Univ., Maidashi 3-1-1, Higashi-ku, Fukuoka 812, Japan); Yamada, H.; Harada, S.; Harada, Y.; Takamoto, M.; Sugiyama, K. *Jpn J Exp Med* 47(6): 435-440; 1977.

The effects of BCG and wax D (extracted from *Mycobacterium tuberculosis* H$_{37}$Ra) on tumor development were investigated in male C3H/He mice treated with a single sc injection of 0.5 mg methylcholanthrene (MC). Doses of 1 mg BCG and 300 μg wax D were used. BCG given 8 wk after MC administration conferred significant protection against carcinogenesis. However, when given either on the same day as MC injection or 4 wk later, a slightly increased tumor incidence was noted. Wax D provided a marked protection against tumor development when given 4 wk after MC, but enhanced tumor development was noted when wax D was administered either on the day of MC treatment or 8 wk later. The protection against tumor development corresponded to a BCG- or wax D-induced increase in the level of delayed-type hypersensitivity at the beginning of tumor development. The enhancing of tumor development corresponded to an induced increase in antibody formation at the time of initiation of tumor development. Thus, the effects of BCG and wax D on tumor development vary with the time of administration. (18 refs)

78-4605 **Early Detection of Tumor-specific Antibodies to Mammary Carcinoma.** (Eng) Blair, P. B. (Dept. Bacteriology and Immunology, Cancer Res. Lab., Univ. California, Berkeley, CA, 94720); Lane, M. A. *Int J Cancer* 21(4): 476-481; 1978.

The antigenic uniqueness of the mammary tumor virus (MTV)-induced mammary tumors of female BALB/cfC3H mice was studied. Sera from 18 tumor-bearing females were used in a microcytotoxicity assay designed to detect immune responses directed against MTV-associated antigens. The sera were tested on both the autologous tumor and on two to three different isologous tumors. There was no evidence of cross-reactivity with 16/18 serum samples, but 2 of the samples did react with a target tumor other than their own. Neither of these two sera reacted with the two other isologous targets on which they were tested. Serial serum samples from multiparous and virgin BALB/cfC3H females were tested using the same assay. Serum activity against tumor-unique antigenicity was observed in samples taken from mice with visible tumors as well as in samples from multiparous females 1-4 mo before a tumor was detected. This antibody activity was not found in serum samples from virgin and nulliparous females before a tumor became grossly visible. The recruiting factor does not appear to be an antigen-antibody complex. The mechanism of tumor formation may involve a longer preneoplastic or latent neoplastic period in parous females than in virgin females. (25 refs)

78-4606 **Host Immunological Reactivity and Adrenal Cortex Function During the Early Period of Chemical Carcinogenesis.** (Rus) Iakimenko, L. V. (Dept. Immunology Carcinogenesis, Inst. Problems in Oncology, Kiev, USSR); Makarchuk, N. M.; Samundzhan, E. M.; Umanskii, Iu. A. *Biull Eksp Biol Med* 85(3): 349-351; 1978.

The associations between immunological reactivity and the functional state of the adrenal cortex were studied in BALB/c mice with 20-methylcholanthrene (20-MC)-induced immune depression. Animals received im injections of 0.2, 0.5, 1, 1.5, or 2 mg 20-MC in 0.1 ml peach oil; 7 days later, the number of antibody-producing cells (APC) in the spleen and the 11-oxycorticosteroid (11-OCS) content in the blood were assessed. Doses of 0.2, 0.5, and 1 g 20-MC increased the serum 11-OCS content 28, 11, and 9 times, respectively. At 0.2 mg, 20-MC decreased the number of APC by 44%; at 2 mg, it decreased the number of APC by nearly 3.5 times. These findings indicate that adrenal cortex hormones play a certain role in the genesis of carcinogen-induced immune depression. (14 refs)

78-4607 **Identification and Behavior of the Precipitating BLV Antibodies in Sera of Leukotic Cattle.** (Eng) Matthaeus, W. (Federal Res. Inst. Animal Virus Diseases, Tubingen, W. Germany); Kaaden, O. R.; Frenzel, B.; Schlotterer, E. *Int J Cancer* 22(2): 166-173; 1978.

Precipitating bovine leukemia virus (BLV) antibodies isolated from bovine leukemic sera by ion-exchange chromatography, gel filtration, and affinity chromatography were identified as immunoglobulins of the IgG_1 subclass and IgA class. They proved to be different with regard to molecular size and electrical charge. IgG_2 and IgM, as well as low-mol-wt components in the microglobulin regions ($\leq$4S) failed to precipitate BLV antigens. Individual bovine leukemic sera showed different precipitating activities against p24 and gp69 antigens. Precipitating monospecific gp69 antibodies represented the IgG_1 subclass exclusively. Some unidentified antigens in disrupted BLV preparations showed a serological relationship to p24 or gp69. (19 refs.)

78-4608 **Relationship Between Membrane Antigen of Human Leukemic Cells and gp70 Oncornavirus Structural Components. Search for Antibodies to the gp70 Antigen.** (Eng) Toth, F. D. (Inst. Microbiology, Univ. Medical Sch., P.O. Box 17, 4012 Debrecen, Hungary); Vaczi, L.; Rak, K.; Balogh, M.; Jako, J. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 148-149; 1978.

Twelve patients with acute myeloid leukemia (AML), 15 with preleukemic disorders (PL), and 44 healthy controls were tested for the major envelope glycoprotein, gp70, of mammalian leukemia viruses and for antibody with gp70 specificity. WBC from six patients with advanced AML and four with PL reacted with gp70 antisera, indicating the presence of gp70 antigen. Remission of leukemia resulted in the disappearance of the antigen and the appearance of gp70 antibody in 7/12 patients. All serum samples from AML patients with advanced disease were negative for the antibody. Of the nine seronegative PL patients, four developed overt leukemia within 1 yr. No gp70-like antigen was present on the surface of normal WBC, but antibody was detected in the sera of 17 healthy persons. (3 refs)

78-4609 **Intra- and Interspecies Reactivity of Human and Mouse Natural Killer (NK) Cells.** (Eng) Hansson, M. (Dept. Tumor Biology, Karolinska Institutet, S 104 01 Stockholm 60, Sweden); Bakacs, K. K.; Kiessling, R.; Klein, G. *J Immunol* 121(1): 6-12; 1978.

Natural killer (NK) cells can kill certain syngeneic, allogeneic and xenogeneic tumor targets in short-term ^{51}Cr-release assays. In the present study, intra- and interspecies NK activity was analyzed. Ten mouse and five human tissue culture lines were used. In direct cytolytic assays with mouse spleen cells or human peripheral blood lymphocyte (PBL) effectors, intraspecies reactivity was much stronger than interspecies reactivity, as a rule. A certain interspecies activity was obtained, stronger in mouse antihuman (M α H) than in human antimouse (H α M) combinations. In the H α M system, activity was associated with the same type of PBL-derived non-B-non-T cell fraction as in the intraspecies H α H system. The non-B-non-T cell nature of the M α H killer cell has been demonstrated previously. Nonlabeled tumor cells were allowed to compete with isotope-labeled targets in intra- and interspecies cytolytic NK tests. NK-sensitive tumor lines of the same species were superior to xenogeneic competitors in both M α M and H α H tests. In the M α M assay, the competing ability of the same human tumors varied, depending on the genotype of the mouse effector cells. None of the human lines tested competed effectively with strain CBA effectors, but some showed a certain competition with C57BL effectors. In the H α H assay, strong competition was seen with 2/10 xenogeneic mouse tumors tested. (25 refs)

78-4610 **Periodic Loss of Reactivity of a Myeloma Tumor with Cytotoxic Thymus-Derived Lymphocytes.** (Eng) Russell, J. H. (Dept. Biology and Center Cancer Res., MIT, Cambridge, MA, 02139); Hale, A. H.; Ginns, L. C.; Eisen, H. N. *Proc Natl Acad Sci USA* 75(1): 441-445; 1978.

During each transplantation passage of a BALB/c mouse plasmacytoma (MOPC-315) through syngeneic mice, the tumor cells lost their reactivity with cytotoxic T lymphocytes directed against the products of the BALB/c major histocompatibility complex (*H-d*). However, this reactivity was regained upon tumor transfer to fresh hosts. In contrast to this cyclical change, MOPC-315 cells remained uniformly reactive with anti-H-2d alloantisera throughout the transplantation cycle. It is not clear whether the periodic loss of reactivity with anti-H-2 cytotoxic T cells represents a mechanism by which the tumor evades destruction by cell-mediated immune responses or reflects a normal differentiation sequence in the maturation of B lymphocytes. (19 refs)

78-4611 **Genetic Resistance to Friend Leukemia Virus in Mice: Masking of *Fv-2* Phenotype by an Epistatic Gene, *Fv-4*^{r}.** (Eng) Odaka, T. (Dept. Genetics, Inst. Medical Science, Univ. Tokyo, Shirokanedai, Minato-ku, Tokyo 108, Japan); Ikeda, H. *Jpn J Exp Med* 47(6): 515-521; 1977.

The *Fv-2* genotype of G mice was investigated by crossing G mice with *Fv-2*^{rr} mice. Both of these strains resist the induction of spleen foci or splenomegaly by Friend leukemia virus, but NB-tropic Friend virus replicates well in the latter and not at all in the former. The (G x *Fv-2*^{rr})F$_1$ hybrids were similar to G. In the F$_1$ x *Fv-2*^{rr} backcross generation, three types of mice appeared: (1) G-type, (2) *Fv-2*^{rr}-type, and (3) *Fv-2*^{SS}-type. Mice of the last type supported virus replication and developed splenomegaly. Mice of types 1, 2, and 3 appeared at the expected ratio of 2:1:1. It is concluded that in G mice, the *Fv-4*^{r} gene suppresses NB-tropic Friend virus replication and thus masks the expression of the *Fv-2*^{S} gene. Studies of the F$_2$ generation support this conclusion. (14 refs)

78-4612 **Immunological Aspects of Mycosis Fungoides.** (Rus) Lezvinskaya, E. M. (Dept. Dermatology, Central Skin and Venereologic Inst., Moscow, USSR). *Vestn Dermatol Venerol* (2): 21-24; 1978.

The blast transformation reaction (BTR) and autoradiography were used to evaluate the functional state of lymphocytes in 30 patients with mycosis fungoides (MF). The indices of lymphocyte transformation were significantly reduced in patients with Stage III MF (30.0%, compared with 55.5% in healthy controls); BTR in patients with Stages I and II MF was similar to that in controls. Patients with an erythrodermoid variant of MF had a marked inhibition of cellular immunity. (29 refs)

78-4613 **Evaluation of the Efficiency of Immune Surveillance in Mice (Meeting Abstract).** (Eng) Patek, P. Q. (Salk Inst. for Biological Studies, San Diego, CA, 92112); Collins, J. L.; Cohn, M. *Fed Proc* 37(6): 1280; 1978. (no refs)

78-4614 **Cellular Interaction Between Cytotoxic and Suppressor T Cells Against Syngeneic Tumors**

in the Mouse. (Eng) Fujimoto, S. (Labs. Immunology, Chiba Univ. Sch. Medicine, Chiba, Japan); Matsuzawa, T.; Nakagawa, K.; Tada, T. *Cell Immunol* 38(2): 378-387; 1978.

The activities of suppresor (sup) and cytotoxic (cyt) T cells against syngeneic tumors (spontaneous lymphoma L1117, methylcholanthrene-induced sarcomas S1509a and SaI) and the modes of interaction between these two cell types in the efferent stage of tumor immunity were determined using A/J mice. An in vitro system was established in which both activities could be estimated simultaneously. Cyt T cells against the tumor lines were induced in vitro by culturing normal spleen and lymph node cells with mitomycin C-treated syngeneic tumor lines. After in vitro stimulation, L1117 lymphoid cells were activated to kill specifically the homologous and closely related tumor cell lines. In addition, the addition of spleen cells from mice bearing the homologous, but no heterologous, tumor to the mixture of cyt and target cells specifically inhibited the T-cell-mediated cyt reaction. With the sarcomas, however, the cyt T cell activated by S1509a or SaI could kill both tumors to the same extent, but the sup T cells from hosts bearing either one of these tumors specifically inhibited the cyt reaction against the homologous tumor but not the cross-reactive one. Sup T cells from tumor bearers possessed Ia antigen controlled by a gene in the *I-J* subregion of the major histocompatibility complex (*H-2*). Cyt T cells generated by some but not all syngeneic tumors were, like sup cells, killed by anti-Ia and complement; however, the Ia antigen on these cyt T cells was controlled by a locus in the *I-A* subregion. The newly established L1117 and S1509a lines induced Ia-positive cyt T cells, whereas the older SaI line, which was capable of growing across the *H-2* barrier, induced Ia-negative cyt T cells. The results indicate that tumor-specific resistance depends on the balance of activation of cyt and sup T cells with different specificities and phenotypic expressions. (21 refs)

78-4615 **Serologic and Immunochemical Characterization of an Immunosuppressive Soluble Factor from Mastocytoma-bearing Mice.** (Eng) Watanabe, M. (Dept. Microbiology, Albert Einstein Medical Center, York and Tabor Roads, Philadelphia, PA, 19141); Pan, S. H.; Friedman, H. *J Natl Cancer Inst* 61(1): 249-254; 1978.

An immunosuppressive (IS) soluble factor from P815-X2 mastocytoma-bearing DBA/2 mice was characterized by serologic and immunochemical tests. The ascitic fluid from mastocytoma-bearing mice depressed the antibody response to sheep RBC. Antisera prepared against ascitic fluid in rabbits neutralized the IS property of the ascitic fluid. Furthermore, antisera prepared in rabbits immunized with concentrated cell-free culture fluid also neutralized the IS activity of ascitic fluid, which indicated some immunologic relationship between the ascitic fluid and the culture supernatants in terms of IS material. Antisera prepared against extracts of intact tumor cells grown in vivo similarly neutralized the ascitic fluid from tumor-bearing mice, also suggesting a relationship between the IS moiety directly extractable from tumor cells grown sc and/or ip and the cell-free ascitic fluids. Immunoelectrophoretic studies with rabbit serum absorbed with normal DBA/2 serum proteins indicated that a distinct precipitin band could be obtained with the ascitic fluid from the tumor-bearing mice. This precipitin band could be dissociated into two separate precipitin arcs by treatment with proteolytic enzymes, but not with other enzymes. Sephadex G-200 gel filtration at neutral pH indicated that the ascitic fluid could be separated into three peaks. Testing for IS activity showed that all plaque-forming cell-impairing activity had shifted from the first peak (containing high-mol-wt globulins, especially α-globulins) to the third peak (containing lower-mol-wt material) when pH 3.6 buffer was used. After acid dissociations, the mol wt of the IS material was $\leq$5,000, a range similar to that of dialyzable IS material found in culture fluids of mastocytoma cells grown in serum-free medium. It is possible that this low-mol-wt material may be complexed with larger proteins, such as the high-mol-wt carrier α-globulins. (16 refs)

78-4616 **Serum-blocking Factors in Human Prostatic Carcinoma.** (Eng) Kouttab, N. M. (Dept. Molecular Carcinogenesis and Virology, Univ. Texas System Cancer Center, M.D. Anderson Hosp. and Tumor Inst., Houston, TX); Bowen, J. M.; von Eschenbach, A. C.; Johnson, D. E.; Bracken, R. B.; Dmochowski, L. *Cancer Bull* 30(4): 115-118; 1978.

Over 50 sera from patients with prostatic cancer and at least 30 sera from normal donors were analyzed for the presence of blocking (factor(s) that abrogate T-cell-mediated immunity against a target cell). The identity of the factor has not been established and it is not known whether a single factor or multiple factors may be involved. Lymphocyte stimulation by phytohemagglutinin (PHA) and mixed leukocyte cultures (MLC) were used as in vitro assays of T-cell function. In the first assay, the sera of patients with prostatic carcinoma were significantly more inhibitory than normal sera. Fractionation of the sera from the patients and normal donors on Sephadex G200 columns demonstrated at least two factors, one of high mol wt (> 160,000) and one of lower mol wt (50,000-70,000). In the MLC assay, a 60% mean inhibition was obtained with sera from the patients, but the mean inhibition with normal sera did not exceed 14%. It is evident that prostatic cancer is responsible for the presence of significant concentrations of an inhibitory factor(s). However, not all sera of prostatic cancer patients contain high concentrations of this factor. It was concluded that most of the inhibitory activity was due to a high-mol-wt factor that is neither an antibody nor an antigen-antibody complex. (5 refs.)

78-4617 **Hormonal Environment of Immunosuppressed Mice.** (Eng) Williams, G. (Urological Unit, Dept. Surgery, Royal Postgraduate Medical Sch., Hammersmith Hosp., London W12 OHS, England); Ghanadian, R.; Papadopoulos, A. S.; Castro, J. E. *Br J Cancer* 37(1): 123-125; 1978.

Serum concentrations of estradiol, progesterone, and testosterone were measured by radioimmunoassay in normal male and female mice aged 9 and 17 wk and compared with those in mice of similar age who had been made deficient in cell-mediated immunity when 3-4 wk old. In 9-wk-old female mice, there was no significant alteration of serum hormone concentrations in the immunodeficient and normal groups. In 17-wk-old immunosuppressed female mice, there were significantly lower serum estradiol concentrations but no difference in serum testosterone or progesterone concentrations. In 9-wk-old immunodeficient male mice, there was a significant increase in serum progesterone and a significant decrease in serum testosterone concentration compared with normal male mice. Both these differences disappeared by 17 wk. Serum hormone concentrations of male and female mice varied widely in comparison with similar human values, which may account for the failure of certain hormone-dependent tumors to grow in immunosuppressed mice. (12 refs)

78-4618 **Friend Virus-induced Immunodepression: Effect of Neuraminidase Treatment on Thy-1.2 Antigen Expression and Cytotoxic Potential of Splenocytes from Virus-infected Mice.** (Eng) Mascio, A. A. (Dept. Zoology, Drew Univ., Madison, NJ, 07940); Ceglowski, W. S. *Infect Immun* 19(2): 486-492; 1978.

Infection of susceptible female C57Bl/6 and DBA mice with Friend leukemia virus (FLV) resulted in a profound depression of cell-mediated immunity, as assessed by lymphocyte-mediated cytotoxicity. This depression occurred early in the disease, before the onset of splenomegaly, and it was associated with a decline in the susceptibility of splenocytes from FLV-infected mice to lysis by anti-Thy-1.2 serum and complement. Treatment of splenocytes from FLV-infected mice with neuraminidase restored, in large part, their susceptibility to anti-Thy-1.2 serum as well as their cytolytic capacity. These studies suggest that one early immunosuppressive consequence of infection with FLV involves alteration of the effector T-lymphocyte cell surface. (32 refs)

78-4619 **Mechanism of Genetic Resistance to Friend Virus Leukemia in Mice. IV. Identification of a Gene (*Fv-3*) Regulating Immunosuppression In Vitro, and Its Distinction from *Fv-2* and Genes Regulating Marrow Allograft Reactivity.** (Eng) Kumar, V. (Dept. Pathology, Boston Univ. Sch. Medicine, Boston, MA, 02118); Goldschmidt, L.; Eastcott, J. W.; Bennett, M. *J Exp Med* 147(3): 422-433; 1978.

Friend murine leukemia virus (FLV) suppresses the proliferative response of normal lymphocytes to mitogens. The suppression of the mitogenic response is mediated by T suppressor cells and is under genetic control. Genetic analyses using resistant and susceptible parental strains F_1 hybrids, and F_2 intercrosses indicated that susceptibility to in vitro suppression is regulated by a single autosomal gene, *Fv-3*. This gene, which is not linked to the *H-2* histocompatibility complex, segregated independently of the *Fv-2* gene that controls resistance to spleen focus formation in vivo. The gene is also not linked to the immune response genes that regulate the ability of *H-2d* mice to reject *H-2b* bone marrow grafts. *Fv-3* may regulate the numbers and/or functions of T suppressor cells. (24 refs)

78-4620 **Murine Lymphoma-induced Immunosuppression: Requirement for Direct Tumor Cell Contact.** (Eng) Cimprich, R. S. (Dept. Microbiology and Immunology, Albert Einstein Medical Center, Philadelphia, PA, 19141); Specter, S.; Friedman, H. *Science* 200(4337): 60-61; 1978.

FBL-3 lymphoma cells, derived originally from leukemia virus-resistant C57BL/6 mice inoculated at birth with Friend leukemia virus, were examined for their effects on the murine immune response system. Ip injection of as few as 10 FBL-3 cells into C57BL/6 mice resulted in death from lymphoma within 30 days. Depression of antibody formation to challenge with sheep RBC occurred after tumor cell inoculation: tumor-bearing mice showed a progressive decline in antibody formation as a function or time after FBL-3 injection. Spleen cells from normal C57BL/6 mice were then cultured to determine the nature of the immunosuppression. Immunization of the spleen cells with 0.1 ml of a 0.1% suspension of sheep RBC resulted in the rapid appearance of hemolytic plaque-forming cells (PFC). Cocultivation of the normal spleen cells with FBL-3 cells resulted in a marked reduction in the antibody response: 500,000 tumor cells produced a 95% suppression of this response. Prior treatment of intact tumor cells with ≥1,000 rads or with heat (56 C) for 20-30 min completely abolished in vivo and in vitro immunosuppressive activity. Tumor cell homogenates had little effect on immunosuppressive activity. Cell-free filtrates showed no suppressive effect. The direct interaction of tumor cells with normal spleen cells appeared to be necessary for suppression of the hemolytic antibody response. (10 refs)

78-4621 **Effect of the *Fv-1* Locus In Vivo: Host Range Pseudotypes of Murine Sarcoma Virus.** (Eng) Otten, J. A. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Myer, F. E.; Tennant, R. W.; Brown, A. *J Natl Cancer Inst* 60(4): 875-880; 1978.

Fv-1-specific host-range pseudotypes of murine sarcoma virus (MuSV) were developed by rescue from nonproducer cells with N- or B-tropic leukemia viruses. The MuSV(B) and MuSV(N) pseudotype viruses were tested in vitro and were restricted specifically by the *Fv-1* gene locus. When the pseudotype viruses were tested in vivo in mice of specific *Fv-1* genotypes, tumor induction was completely restricted in nonpermissive animals, including athymic nude mice. However, all tumors grew progressively in permissive animals. All tumors regressed in adult heterozygous mice, but not in adult athymic nude mice. These results confirm that the MuSV(B) and MuSV(N) host-range pseudotype viruses are subject to the same intracellular restriction as the N- or B-tropic helper leukemia viruses. Furthermore, the *Fv-1* gene restricts the MuSV(N) pseudotype virus in the absence of a competent thymic function. (19 refs)

78-4622 **Are Tumor-associated Transplantation Antigens of Chemically Induced Sarcomas Related to Alien Histocompatibility Antigens?** (Eng) Pliskin, M. E. (Sch. Dental Medicine, Univ. Pennsylvania, 4001 Spruce St., Philadelphia, PA, 19104); Prehn, R. T. *Transplant Proc* 26(1): 19-24; 1978.

The hypothesis that tumor-specific transplantation antigens of chemically induced tumors cross-react with allogeneic histocompatibility antigens was tested. This hypothesis makes several predictions that can be tested experimentally. First, tumors should grow better and be less immunogenic in certain F_1 hybrids than in their syngeneic parents, owing to the hypothecated cross-reactivity of the tumor-specific transplantation antigens with F_1 antigens. This is in contrast to the more common observation that parental strain tumors grow worse in the F_1 hybrids than they do in the parent. Also, certain allogeneic skin grafts might immunize the parental strain mice against their syngeneic tumors, and, finally, immunizing parental mice with syngeneic tumors might cause accelerated rejection of certain skin allografts. The results show that certain methylcholanthrene-induced sarcomas grew better in C/C3H F_1 mice than they did in the BALB/c parents but that the tumors were not less immunogenic in the F_1 hybrids. Mice immunized against alloantigens showed a dose-dependent enhancement of syngeneic tumor growth. Finally, mice immunized with syngeneic tumors demonstrated an apparent prolongation of certain skin allografts. Possible alternatives explaining these results are considered. (50 refs.)

78-4623 **Temperature Sensitivity of the Specific Transplantation Antigens of Tumor Cell Membrane.** (Rus) Kliuchareva, T. E. (Lab. Tumor Immunology, Cancer Res. Center, Moscow, USSR). *Biull Eksp Biol Med* 85(3): 351-353; 1978.

A study was made of the effect of temperature on the immunogenic properties of the tumor-specific transplantation antigen (TSTA) in simian virus 40 (SV40)-induced tumors. The tumor cells were incubated at 37 C and 56 C for 30 min, irradiated at 12,000 rads, and then injected into syngeneic hamsters. The immunogenic properties of the TSTA were assessed by a transplantation test. Administration of irradiated cells incubated at 37 C to hamsters significantly increased their specific resistance; incubation of cells at 56 C resulted in complete inactivation of TSTA. (7 refs)

78-4624 **Protection Against Syngeneic Tumor Grafts Induced by Inoculation with Normal Allogeneic Tissues.** (Eng) Bear, R. H. (Dept. Immunology Res., Roswell Park Memorial Inst., Buffalo, NY, 14263); Roholt, O. A.; Pressman, D. *Immunol Commun* 6(6): 547-558; 1977.

The protection offered by sc injection of normal allogeneic kidney and liver tissues against syngeneic tumor grafts was investigated in DBA/2Cr mice. Female mice were given x χ 10^4 viable methylcholanthrene-induced L5178Y lymphoma cells ip and 0.5 ml of an allogeneic mixture of liver and kidney tissues from BALB/cCr, A/J, C57BL/6Ha, ARK/Sn, and DBA/2Ha-DD mice. Following challenge and immunization, 42% of the mice were alive after 100 days; controls immunized with syngeneic DBA/2Cr kidney and liver tissue survived a mean of 13 days. X-irradiation of the allogeneic cell mixture (10^4 R) prior to immunization gave the same protection as the unirradiated mixture. The allogeneic mixture did not confer protection against 10^4 L1210 cells in DBA/2Cr mice, but it did confer partial protection against 10^6 L1210 cells in DBA/2Ha-DD mice. A combination of 2 ml of the allogeneic mixture and 8 ml of the syngeneic cells was also administered, and 86% of the mice were alive 100 days after challenge. The protection was comparable to that obtained by immunization with irradiated L5178Y tumor cells. Analysis of the protection conferred by each individual strain indicated that none of the strains alone were as effective as the allogeneic mixture from the five different strains. Therefore, the protection is potentiated when the tissues are combined. It is suggested that this protection is the result of a cross-reactivity or identity between L5178Y tumor-associated transplantation antigens and nonhistocompatibility alloantigens normally expressed by some allogeneic tissues. (16 refs)

78-4625 **Loss of Oncogenicity and Concomitant Increased Immunogenicity of Murine Plasmacytoma Cell Lines.** (Eng) Sorenson, G. D. (Dept. Pathology, Dartmouth Medical Sch., Hanover, NH, 03755); Pettengill, O. S.; Cate, C. C. *Am J Pathol* 90(3): 565-582; 1978.

Long-term observations of BALB/c mouse MOPC-21 and MOPC-315 plasmacytoma cells showed that the cells lost their oncogenicity with increasing time in culture. Newly established cultures were oncogenic and caused lethal tumors in syngeneic mice. Later, although the cultures were still oncogenic, some of the tumors regressed. Eventually, the cultures became nononcogenic in normal mice, but they did cause tumors in irradiated mice. Clones from the cultures varied from being very oncogenic to nononcogenic. It appears that the nononcogenic cells have a selective growth advantage and that they become the dominant cell type in the cultures. Nononcogenic cultures were more effective for immunization to subsequent challenge with the original tumor than were the tumor cells or oncogenic cultures. They appeared to confer complete protection against lethal tumor challenge in adoptive transfer experiments. Mixtures of nononcogenic and oncogenic cells decreased the tumor-forming ability of the latter when they were injected together in one site or separately in two sites. (39 refs)

78-4626 **Chromosomes of Lymph Node Metastases Derived from Ehrlich Ascites Carcinoma Cells Inoculated into Rats.** (Eng) Olinici, C. D. (Inst. Oncology, R-3400 Cluj-Napoca, Romania); Risca, R.; Todorutiu, C. *Z Krebsforsch* 90(3): 281-284; 1977.

Chromosomes from lymph node metastases in female Wistar rats that had received 100 x 10^6 Ehrlich ascites tumor cells ip were examined. The rats were given 600 R whole-body irradiation 1 day before inoculation and five ip injections of 5 mg cortisone (total dose 25 mg) starting on the day of inoculation. The animals were sacrificed 7 and 15 days after grafting. The incidence of rat cells in the ascites fluid increased from 16% on day 7 to 36% on day 15. The incidence of rat metaphases was considerably greater in the lymph nodes: 29% on day 7 and 69% on day 15. Chromosome-banding analysis indicated that the tumor cells in the lymph nodes had the typical constitution of Ehrlich cells, as ascertained by three marker chromosomes. No host-derived chromosomes were noted in these cells. The rat cells contained 42 species-characteristic chromosomes. (8 refs)

78-4628 **Genetic Analysis of Tumorigenesis: Expression of Tumor-Forming Ability in Hamster Hybrid Cell Lines.** (Eng) Sager, R. (Sidney Farber Cancer Inst., Dept. Microbiology, Harvard Medical Sch., Boston, MA); Kovac, P. E. *Somatic Cell Genet* 4(3): 375-392; 1978.

The characteristics of two new fibroblast cell lines and hybrids formed between these lines were studied. The two cell lines, which were established from a Chinese hamster embryo, were designated CHEF 16-2 and CHEF 18-1. The cell lines differed in colony morphology, plating efficiency, anchorage dependence of growth, tumorigenic potential in nude mice (16-2 was tumorigenic and 18-1 was not), and modal chromosome number. The most striking difference was that the 16-2 cells cloned at high frequencies (30%-60%) in methylcellulose but the 18-1 cells did not form colonies at a detectable frequency ($< 10^{-5}$). Mutagenesis in ethylmethane sulfonate (EMS) and selection of 6-thioguanine (TG)-resistant 18-1s and 5-bromo-2-deoxyuridine (BUdR)-resistant 16-2s lines did not alter the principal distinguishing properties of the parental lines. The 22 chromosomes in both parental lines consisted of 10 pairs of homologous autosomes plus an X and a Y. As few as 10 CHEF 16-2 cells gave rise to tumors in nude mice, provided that they were coinjected with x-irradiated 18-1s cells, which fulfilled an unknown function. Hybrid colonies more closely resembled the nontumorigenic parent than the tumorigenic parent, and each hybrid clone was a mixture of cells with different levels of anchorage dependence. The 19 hybrid clones tested were unambiguously tumorigenic in the nude mouse, although they showed a heterogeneity in rate of tumor formation. Nine subclones derived from three hybrid lines showed a decrease in chromosome number from the tetraploid range of the hybrids to the diploid range. The tumor subclones appeared to be tumorigenic subsets in the suppressed hybrid populations. Evidence that the hybrids were of hybrid rather than parental origin is provided. (30 refs.)

78-4631 **A Mammalian Cellular System for the Concomitant Study of Neoplastic Transformation and Somatic Mutation.** (Eng) Barrett, J. C. (Natl. Inst. Environmental Health Sciences, NIH, P.O. Box 12233, Research Triangle Park, NC, 27709); Bias, N. E.; Ts'o, P. O. *Mutat Res* 50(1): 121-136; 1978.

Neoplastic transformation and somatic mutation were studied in strain LSH/ssLAK Syrian hamster embryo cells. Chemically induced somatic mutation was assayed at two genetic loci: mutants deficient in hypoxanthine phosphoribosyltransferase (HPRT) were detected by the production of colonies resistant to 40 μg/ml 8-azaguanine (AG-r) or 2 μg/ml 6-thioguanine (TG-r); mutants with an altered Na^+/K^+ ATPase were detected by the production of colonies resistant to 1.25 mM ouabain (Oua-r). The results showed that AG-r/TG-r cells possess a mutation in a structural or regulatory gene for HPRT and that the Oua-r cells have an altered Na^+/K^+ ATPase. This finding is based on the evidence that: (1) the isolated clones had stable, heritable resistance to the selective drugs; (2) the AG-r clones were cross-resistant to 6TG; (3) the reversion frequency of the AG-r and TG-r clones was $< 10^{-6}$; (4) the HPRT activity of the AG-r/TG-r clones was $< 1\%$ of the parental cells; (5) Oua-r clones showed decreased sensitivity to Oua inhibition or ^{86}Rb uptake (compared to wild-type cells) and they maintained their resistance to Oua; and (6) the frequency of resistant clones was increased by known mutagens in a dose-dependent manner. Factors involved in quantification of the mutation frequencies of the embryo cells were determined following exposure of the cells to benzo(a)pyrene (BP: 1 or 10 μg/ml) or N-methyl-N′-nitro-N-nitrosoguanidine (MNNG: 1 or 5 x 10^{-6} M). BP or MNNG treatment before selection increased the frequency of resistant colonies significantly. This system allows a quantitative comparison of the frequencies of somatic mutation and morphological transformation. (42 refs)

78-4632 **Presence of Retinoic Acid-Binding Protein in Experimental Tumors and in Tissues with Metastatic Tumor (Meeting Abstract).** (Eng) Sani, B. P. (Southern Res. Inst., Birmingham, AL, 35205). *Proc Am Assoc Cancer Res* 19: 19; 1978. (no refs)

78-4633 **Some Mechanisms Involved in Cancer Cell Detachment by Necrotic Material.** (Eng) Weiss, L. (Dept. Experimental Pathology, Roswell Park Memorial Inst., Buffalo, NY, 14263). *Int J Cancer* 22(2): 196-203; 1978.

Previous studies of cylinders punched from Walker 256 (W-256) tumors growing in rats showed that detachment of viable cancer cells was facilitated by their proximity to necrotic regions and exposure to a necrotic extract. In these experiments, pure cultures of W-256 cells were used to show that necrotic extracts that are rich in lysosomal hydrolases act directly on W-256 cells, facilitating their in vitro detachment. Lysosomal enzymes are known to facilitate cell detachment. The partial inhibition of this process by hydrocortisone suggests that the extracts also acted by labilizing the W-256 cell lysosomes; this enzyme release was also demonstrable by direct assay. Although secondary lysosomes could not be visualized in the W-256 cells, both they and macrophages released lysosomal hydrolases upon freeze-thawing. Both could account for the high enzyme content of the necrotic regions, by a process of continuous secretion and/or by cell input. Histologic examination of the perinecrotic and peripheral regions of tumors showed a higher proportion of macrophages in the former, probably because of differential trapping of the macrophages. The results emphasize the functional properties of necrotic tumor regions and the necessity of referring to specific regions of the same tumor when alluding to its metastatic and other properties. (35 refs.)

78-4638 **Characterization of a Suppressor-Cell Leukemia. Evidence for the Requirement of an Interaction of Two T Cells in the Development of Human Suppressor Effector Cells.** (Eng) Broder, S. (Metabolism Branch, NCI, Bethesda, MD 20014); Poplack, D.; Whang-Peng, J.; Durm, M.; Goldman, C.; Muul, L.; Waldmann, T. A. *N Engl J Med* 298(2): 66-72; 1978.

The suppressor-cell activity of neoplastic T cells from an 11-mo-old boy with acute lymphoblastic leukemia and hypogammaglobulinemia was investigated. The patient's leukemic cells did not secrete detectable immunoglobulin (Ig) in vitro, but the lymphocytes of 12 normal persons secreted 3,200 nanogram (ng) of IgM, 1,825 ng of IgA, and 2,447 ng of IgG. The addition of neoplastic or irradiated neoplastic T cells to normal B cells did not stimulate Ig synthesis, indicating that the T cells were not committed to express helper activity. However, the cells were committed to suppressor activity, as the addition of 10^6 neoplastic lymphocytes profoundly suppressed Ig synthesis in equal numbers of lymphocytes from six normal persons. Suppressor cell activity was nullified by prior irradiation (2,000 R), and it was a function of the number of the neoplastic cells added to the normal cells. In a pokeweed mitogen-stimulated system of Ig secretion, neoplastic T cells caused suppression only when unirradiated normal T cells were provided. When irradiated or unirradiated normal T cells were added as a source of helper activity, Ig production returned to normal for the unseparated lymphocytes. These findings indicate the existence of two populations of radiosensitive cells: the neoplastic T cells from the patient and a subset of cooperating normal T cells. (28 refs.)

78-4639 **Studies of Genetic Suppression of AKR Mouse Leukemia.** (Eng) Lilly, F. (Dept. Genetics and Pathology, Albert Einstein Coll. Medicine, Bronx, NY, 10461); Duran-Reynals, M. L.; Mayer, A. J.; Bosch, A. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 55-59; 1978.

Crosses between various low-leukemic mouse strains and the high-leukemic AKR strain were studied to determine relationships between the occurrence of spontaneous leukemia and the genetically controlled expression of ecotropic and/or xenotropic murine leukemia viruses (MuLV) in lymphoid tissues. The incidence of leukemia in the F_1 progeny resulting from AKR x ST/b crosses essentially paralleled that in AKR mice, indicating that ST/b mice possess no dominant gene(s) capable of suppressing the AKR phenotypes under consideration. However, F_1 mice of the AKR x BALB/c cross showed a leukemia incidence of $<5\%$, indicating that one or more dominant genes of the BALB/c complement must be capable of suppressing this phenotype. The phenotype appears to be a function of the Fv-1b allele. F_1 progeny of the AKR x RF/J cross showed high levels of infectious ecotropic MuLV but a low incidence of leukemia. The results of backcrosses of (AKR x RF) with AKR suggested that the Fv-1 allelle of RF mice is capable of suppressing the AKR leukemia phenotype. The allele may exert its effect by suppressing the expression of xenotropic MuLV. The data suggest that the expression of both ecotropic and xenotropic viruses is necessary for AKR leukemogenesis. (15 refs.)

78-4640 **Changes in the Karyotype of Bone Marrow Cells in the Progeny of Leukemic Cows.** (Rus) Burba, L. G. (All-Union Inst. Experimental Veterinary Medicine, Moscow, USSR); Dun, E. A.; Simonian, G. A. *Veterinariia* (3): 43-46; 1978.

The bone marrow and blood cells of 22 calves born to leukemic cows were investigated at 3-mo intervals. Changes in the chromosome complement of the bone marrow cells as well as subleukemic and leukemic changes in the blood were found in 27% of the calves. Considerable deviation from the diploid cells, which ranged from 40% to 70%, tended to rise with age. The number of hypodiploid and hyperdiploid metaphases increased significantly, but the percentage of aneuploid metaphases decreased with age. The findings confirm the significance of genetic disposition in leukemogenesis. (no refs)

78-4641 **Karyotypic Analysis of Lymphoid Blood Cells in Leukemic Cows.** (Rus) Birbin, S. S. (Veterinary Res. Station, Saratov, USSR). *Veterinariia* (5): 37-40; 1978.

The incidence of chromosome aberrations was studied in 39 leukemic cows, 24 in the initial (hematologic) stage and 15 in the advanced stage (hyperplasia of lymphoid tissue and the spleen). All of the latter had chromosome aberrations (predominantly in lymphoid blood cells). The aberrations included hyperploidy (85%-99% of examined metaphases; 11/15 cows had 61 chromosomes (compared with 60 chromosomes in the normal complement)) and chromosome rearrangements (metacentric and submetacentric chromosomes). (no refs.)

78-4642 **Cellular Maturation in Human Preleukemia.** (Eng) Koeffler, H. P. (Div. Hematology-Oncology, Dept. Medicine, UCLA Sch. Medicine, Los Angeles, CA, 90024); Golde, D. W. *Blood* 52(2): 355-361; 1978.

Bone marrow cells from three preleukemic patients (1 woman aged 25, 2 men aged 78 and 79) with prominent marrow karyotypic abnormalities were studied in liquid culture to determine if the neoplastic clones were capable of maturation. Parallel cytogenetic and cytologic studies were performed in sequentially harvested bone marrow cultures. Maturation, albeit delayed, occurred in cultures from all three patients. By 14 days of culture in vitro, morphologic, cytochemical, and functional evidence of maturation was observed in about 70% of the cells. By day 21, 85% of the cells were mature. All but 2 of 249 metaphases from the cultured cells contained the cytogenetic abnormality of the neoplastic clone. It is concluded that some preleukemic cells identified by a chromosomal abnormality can mature in vitro. Preleukemia may be viewed as a syndrome of 'early leukemia' in which the neoplastic clone is established and manifested functionally as ineffective hematopoiesis. Hematopoietic cell differentiation becomes progressively abnormal, terminating in the nearly complete maturational block characteristic of acute myelogenous leukemia. (30 refs.)

78-4643 **Blood Dyscrasias and Childhood Tumors and Exposure to Chlordane and Heptachlor.** (Eng) Infante, P. F. (Office Carcinogen Identification and Classification, Occupational Safety and Health Admin., U.S. Dept. Labor, 3rd and Constitution Ave., NW, Washington, DC, 20210). *Scand J Work Environ Health* 4(2): 137-150; 1978.

Pathological conditions possibly associated with exposure to chlordane- and heptachlor-containing pesticides are discussed. Five recently diagnosed cases of neuroblastoma associated with chlordane exposure during prenatal and postnatal development are summarized, as are three cases of aplastic anemia and three cases of acute leukemia associated with chlordane formulations. The neuroblastoma cases are of interest in view of recent data on the carcinogenicity and mutagenicity of chlordane and heptachlor and data on environmental distributions and body burdens. The aplastic anemia and leukemia cases are of interest in view of previous reports on associations between chlordane and similar chlorinated hydrocarbon pesticides and blood dyscrasias and reports indicating that some subjects with aplastic anemia convert to leukemia. There is need for a formal epidemiologic study to evaluate the health risks associated with domestic and occupational exposure to chlordane. (63 refs)

78-4644 **Acute Myeloid Leukaemia with Monosomy-7 Follows Acute Lymphoblastic Leukaemia.** (Eng) Secker Walker, L. M. (Dept. Cytogenetics and Immunology, Royal Marsden Hosp., Fulham Road, London SW3 6JJ, England); Sandler, R. M. *Br J Haematol* 38(3): 359-366; 1978.

The case report of an 8-yr-old girl who developed acute myeloid leukemia (AML) following the successful treatment of acute lymphoblastic leukemia (ALL) is presented. She presented with ALL at the age of 5. Remission was induced with prednisolone, vincristine, radiation (2,400 rads to the cranium, 1,000 rads to the spine), and intrathecal methotrexate. She remained well on maintenance therapy, including 600 mg/m^2 cyclophosphamide every 12 wk, for 2 yr, at which time she became pancytopenic with marrow depression. Bone marrow remission was induced by the cessation of chemotherapy, but the pancytopenia remained. Marrow cells monosomic for chromosome 7 (45 XX-7) were first noted 2 mo before the onset of progressive pancytopenia when blood parameters were normal. During both the pre-leukemic and frankly leukemic states of the myeloid neoplasm, cells with monosomy-7 constituted the dominant cell line in the marrow. This suggests that the pancytopenia was part of the malignant change and that the chromosomal change was an early event in the neoplastic process. Family studies indicated that the patient's paternal grandmother had died of acute leukemia and that there had been a high cancer incidence in her maternal grandfather's generation. It is suggested that genetic factors may have been at least as important as environmental conditions in triggering the second malignancy. (31 refs)

78-4645 **Metamorphosis of Chronic Granulocytic Leukaemia Arising in an Extramedullary Site.** (Eng) Kwan, Y. L. (Medical Res. Dept., Kanematsu Memorial Inst., Sydney Hosp., Sydney, New South Wales 2000, Australia); Singh, S.; Vincent, P. C.; Gunz, F. W. *Leuk Res* 1(4): 301-307; 1977.

The metamorphosis of chronic granulocytic leukemia was followed in a 52-yr-old man. The diagnosis was based on typical leukocytosis, a hypercellular marrow with myeloid hyperplasia, and a single Philadelphia (Ph^1) chromosome in 100% of the marrow metaphases. Elective splenectomy was performed early in the disease because of persistent mild splenomegaly and a tendency toward thrombocytopenia. As the disease progressed, extramedullary leukemic deposits were noted in the stomach, skin, and lymph nodes. Marked chromosome abnormalities (hyperdiploidy and doubling of the Ph^1 chromosome) were noted in a biopsied axillary lymph node at a time when marrow chromosomes showed only a 46XY Ph^1 positive pattern typical of the chronic phase. With disease progression, cells with related chromosome abnormalities appeared in the blood. The sequence of events and cytogenetic changes suggested that the cells responsible for the metamorphosis appeared first in an extramedullary site and spread from there to the marrow and blood. (5 refs)

78-4646 **Genetic and Pathologic Findings in a Kindred with Hereditary Sarcoma, Breast Cancer, Brain Tumors, Leukemia, Lung, Laryngeal, and Adrenal Cortical Carcinoma.** (Eng) Lynch, H. T. (Dept. Preventive Medicine/Public Health, Creighton Univ. Sch. Medicine, Omaha, NB, 68178); Mulcahy, G. M.; Harris, R. E.; Guirgis, H. A.; Lynch, J. F. *Cancer* 41(5): 2055-2064; 1978.

Pathologic and genetic studies were carried out on a family with a hereditary tumor complex characterized by sarcomas, brain tumors, leukemias, and carcinomas of the breast, larynx, lung, adrenal cortex, and other sites. Based on sibships segregating for cancer, the genetic segregation parameter was estimated as 45.5% ± 11%, which is consistent with that expected for a rare deleterious autosomal gene showing complete dominance. A microscopic review of 16 tumors revealed intranuclear cytoplasmic invaginations, intranucleolar bodies, or acidophilic inclusions in 8 lesions. Two tumors showed both intranuclear cytoplasmic invaginations and intranucleolar inclusions. It is hypothesized that the cancer-prone genotype interacts with one or more exogenous factors, including an oncogenic virus, in causing this familial tumor aggregation. (39 refs)

78-4647 **Kaposi's Sarcoma in Renal Allograft Recipients.** (Eng) Stribling, J. (Dept. Surgery, Univ. Mississippi Medical Center, 2500 N. State St., Jackson, MS, 39216); Weitzner, S.; Smith, G. V. *Cancer* 42(2): 442-446; 1978.

Kaposi's sarcoma developed in a 61-yr-old man who had been a renal allograft recipient 9 mo previously. Eight similar cases in the literature are reviewed. In all nine patients, the interval between transplantation and diagnosis of the sarcoma varied from 8 to 43 mo; however, in six patients the interval was 8-12 mo. It was hypothesized that chronic immunologic interaction between normal and antigenically altered or transformed lymphocytes (as in a graft-vs-host reaction) results in the production of an angiogenesis factor that produces intense proliferation of mesenchymal and endothelial cells, eventually leading to Kaposi's sarcoma. It has also been suggested that a chronic low-grade immune response rather than severe crises are important, thus invoking the role of enhancing or blocking factors. Viral etiologies have also been postulated. The patients presented met the criteria of chronic immunologic stimulation, probably had altered lymphocytes because of suppressive therapy, and nearly half developed viral infections. However, development of malignant neoplasms following renal transplantation appears to depend on immunosuppressive therapy, since the oral lesions in three patients and the cutaneous lesions in one regressed completely upon cessation of this therapy. (11 refs.)

78-4648 **Metastatic Heterogeneity of Cells from an Ultraviolet Light-induced Murine Fibrosarcoma of Recent Origin.** (Eng) Kripke, M. L. (Cancer Biology Program, NCI Frederick Cancer Res. Center, Frederick, MD, 21501); Gruys, E.; Fidler, I. J. *Cancer Res* 38(9): 2962-2967; 1978.

The parent line and 21 cell clones isolated from fibrosarcoma 2237 (recently produced by chronic UV irradiation in a female C3H- mouse) were tested in specific-pathogen-free C3H/HeN(MTV-) mice to determine if any variations existed in their metastatic potential. Three different in vivo tests were used: (1) mice were given iv injections of 10^5 tumor cells and killed 18 days later, and tumor colonies in the lungs were counted; (2) mice were given sc injections of 10^6 tumor cells and examined at death for the presence of spontaneous metastases; and (3) mice were given iv injections of 10^6 tumor cells and autopsied at death. The time of death was recorded, and the number and site of metastases were determined. The clones varied greatly in their ability to grow and metastasize following sc or iv inoculation. The three tests gave similar results in that clones judged to be of high or low metastatic potential in one test generally exhibited the same behavior in the other two tests. It was concluded that the parent tumor was heterogeneous and that cells with widely different metastatic potential preexisted in the parental population. The correspondence among the three tests also permitted the conclusion that for this tumor, the quantitative lung colony assay approximated rather well the more tedious measurements of spontaneous metastasis. (24 refs.)

78-4649 **Malignant Melanoma and Genetic Heterogeneity: A New Familial Melanoma Syndrome (Meeting Abstract).** (Eng) Lynch, H. T. (Creighton Univ. Sch. Medicine, Omaha, NB, 68178); Frichot, B. C.; Guirgis, H. A.; Lynch, P. M.; Follet, K. *Proc Am Assoc Cancer Res* 19: 348; 1978. (no refs)

78-4650 **Metastasis, An Experiment with a Transplantable Tumor in F1 Hybrids of C3H x AJ Mice (Meeting Abstract).** (Eng) Pringgoutomo, S. (Dr. Cepto Mangunkusumo Hosp., JL, Diponegoro 71, Jakarta, Indonesia); Suprapti, S. P. *In: Summary Program and Abstracts of Papers. Proceedings of the 3rd Asian Cancer Conference Held by the Philippine Cancer Society under the Auspices of the Asian Federation of Organizations for Cancer Research and Control in Manila, 26-30 September, 1977.* Philippine Cancer Society. (Manila, Philippines): 184 pp.; 128-129; 1977. (no refs)

78-4651 **Serum Genetic Markers in a Newfoundland Isolate with a Familial Aggregate of Hodgkin's Disease.** (Eng) Carter, N. D. (Dept. Child Health, St. George's Hosp., Medical Sch., Cranmer Terrace, London, SW17, ORE, England); van Loghem, E.; Marshall, W. H.; Newton, R. M.; West, C. M. *Hum Hered* 28(5): 372-379; 1978.

Genetic markers [immunoglobin (Ig) allotypes Gm, Am, and Km and three other serum proteins, group-specific component (Gc), transferrin, and haptoglobin] were investigated in members of an isolated Newfoundland community, most of whom (> 1,200) were related. A familial aggregate of lymphoma and immunodeficiency diseases was discovered among individuals that belonged to this extended family. Blood samples from nearly 1,000 individuals were studied. Gene frequencies for the serum proteins showed no significant deviation from European frequencies. The finding of a variant transferrin in six individuals is in accord with the ancestral origin (English) of the community. However, the occurrence of rare phenotypes [A2m(2) and Gm (zfngb)] pointed toward a specific admixture from American Indians and Scandinavians. An American Indian admixture has been documented in the pedigrees. Transmission of the Ig marker Gm (zfngb) to Newfoundland from Scandinavia via the Orkney Islands has been proposed. A possible contribution of these rare alleles and of others to pathogenesis in a familial aggregate of Hodgkin's disease within this community is discussed. The hypothesis is that predisposition to Hodgkin's disease is likely to be based on a complex genotype with contributions from many different loci. This aggregate of cases in an inbred, genetically isolated community suggests that, due to chance, a number of alleles capable of contributing to a predisposition for Hodgkin's disease have come together in this family. (10 refs.)

78-4652 **Intestinal Lymphoma Associated with Malabsorption (Letter to Editor).** (Eng) Cooper, B. T. (Dept. Medicine, Hammersmith Hosp., London W12, England); Holmes, G. K.; Cooke, W. T. *Lancet* 1(8060): 387; 1978.

The results of an unpublished review of 27 patients with lymphoma and celiac disease are in agreement with previous studies, and they indicate that patients with flat jejunal mucosa, malabsorption, and lymphoma should be evaluated for preexisting celiac disease. However, by the time a lymphoma becomes clinically manifest, it is usually too late for a response to a gluten-free diet. (1 ref)

78-4653 **Prostaglandins and Actinic Cancer (Letter to Editor).** (Eng) Smith, E. B. (Dept. Medicine, Sch. Medicine, Univ. New Mexico, Albuquerque, NM, 87131); Mason, W. V.; Goodwin, J. S. *Lancet* 1(8063): 561; 1978.

A role for prostaglandin E_2 (PGE_2) in the pathogenesis of skin tumors is suggested. PGE_2 released in the skin following UV exposure may suppress immune responses in the skin and interfere with immunological surveillance. This effect would offset any protective effects of PG formation. It could also explain the manifestations of viral exanthems in light-exposed skin. (11 refs)

78-4654 **Bone Metastases from Occult Primary Cancer (Meeting Abstract).** (Eng) Shank, B. (Dept. Radiation Therapy, Memorial Sloan-Kettering Cancer Center, New York, NY, 10021); Batata, M. A.; Chu, F. C. *Proc Am Assoc Cancer Res* 19: 314; 1978. (no refs)

78-4655 **Extraneuraxial Canine Meningioma. A Light and Electron Microscopic Study.** (Eng) Vuletin, J. C. (Dept. Pathology, Downstate Medical Center, 450 Clarkson Avenue, Brooklyn, NY, 11203); Friedman, H.; Gordon, W. *Vet Pathol* 15(4): 481-487; 1978.

Light and electron microscopic features of an sc extra-neuraxial meningioma removed from the shoulder of a 7.5-yr-old German Shepherd crossbred male dog are described. No local recurrence or metastases were found 6 mo after surgery. The tumor probably arose from arachnoid cap cells displaced during embryogenesis. (23 refs.)

78-4656 **Granular Cell Tumor of the Brain.** (Fre) Pialat, J. (Laboratoire d'Anatomie Pathologique et Neuropathologie, Faculte de Medecine A. Carrel, Rue Guillaume Paradin, F 69372 Lyon Cedex 2, France); Carrier, H.; Pierluca, P.; Chazot, G.; Trillet, M.; Kopp, N. *Lyon Med* 239(5): 269-274; 1978.

A case is reported of primary granular cell tumor of the brain in a 61-yr-old man. Concerning the pathogenesis of these tumors, a Schwann cell origin seems most probable. (no refs)

78-4657 **Connexions Between Nerves and Intradermal Nevi (Meeting Abstract).** (Eng) Jurecka, W. (Dept. Electron Microscopy, Univ. Vienna, Vienna, Austria); Lassmann, H.; Gebhart, W. *Arch Dermatol Res* 261(1): 91; 1978. (no refs)

78-4658 **Tumor Caused by a Foreign Body in the Nasal Fossa and Maxillary Sinus.** (Pol) Lukomski, M. (Klinika Laryngologiczna, Instytut Chorob Ukladu Nerwowego i Narzadow Zmyslow AM, ul. Kopcinskiego 22, 90-153 Lodz, Poland); Makowski, A. *Otolaryngol Pol* 31(1): 73-75; 1977.

Diffuse squamous cell carcinoma, with chronic inflammation and focal erosion, and a corroded metal object measuring nearly 4 cm in length were found in the left nasal fossa and left maxillary sinus of a 68-yr-old man. He had presented with recurrent headache and exophthalmus of the left eye 3 yr earlier. The carcinoma is believed to have developed from the chronic irritation caused by the metal object and the compounds formed by its corrosion. (13 refs)

78-4659 **Estrogen Profiles in Young Women: Effect of Maternal History of Breast Cancer.** (Eng) Morgan, R. W. (Dept. Preventive Medicine, Univ. Toronto, Toronto, Ontario M5S 1A8, Canada); Vakil, D. V.; Brown, J. B.; Elinson, L. *J Natl Cancer Inst* 60(5): 965-967; 1978.

Estrone (E_1), estradiol (E_2), and estriol (E_3) concentrations were determined in the urine of daughters of breast cancer patients and their matched controls. These findings were then used to compute the estriol proportions (EP; $E_3/E_1 + E_2 +$

E$_3$). For all women, the EP rose to a peak at age 26-30 yr and then declined slightly. Parity had no consistent effect on EP. Study of the daughters and their matched controls showed no differences in EP. It is concluded that the estrogen profile is not an important determinant of familial breast cancer. (10 refs)

78-4660 **Identic Viral Infections in Four Cases of Malignant Lymphoepithelioma.** (Eng) Arnold, W. (ENT Dept., Univ. Dusseldorf, Moorenstrasse 5, D-4000 Dusseldorf, W. Germany). *Arch Otorhinolaryngol (NY)* 220(4): 287-289; 1978.

Electron microscopy of tumor tissue from four patients with malignant lymphoepithelioma of the nasopharynx and tonsil revealed herpesviruslike nucleocapsids in the nucleoplasm and empty capsids in the cytoplasm. These particles were similar to those found in tissue culture lines of Burkitt's lymphoma and nasopharyngeal carcinoma. These findings, together with the observation that Epstein-Barr virus antibody levels change during the course of lymphoepithelioma, suggest a role for a specific viral infection in the disease. (5 refs.)

78-4661 **Clinical Findings and Morphology of Precancerous States and Early Cancers of the Larynx.** (Pol) Szlezak, L. (Oddzial Otolaryngologiczny, Szpital im. Fr. Raszeji ZOZ Poznan-Jezyce, Grodziska 18a m. l., 60-363 Poznan, Poland); Przybora, L.; Ryglewicz, J. *Otolaryngol Pol* 31(3): 305-316; 1977.

Precancerous and cancerous changes of the larynx were studied in 151 patients. Polyps with pachyderma or leukoplakia were found in 28 patients; all smoked 10-20 cigarettes daily. Polyps with pachyderma, cellular dysplasia and early cancer were found in one patient. Pachyderma and leukoplakia were found in 44 patients; all smoked 10-20 cigarettes a day. Pachyderma, leukoplakia with cell proliferation, and dysplasia were seen in 26 patients; all smoked 20-40 cigarettes a day. Pachyderma, leukoplakia with cellular dysplasia, and early cancer were seen in 19 patients. Malignant transformation was found in 11/33 adults with papilloma. (21 refs)

78-4662 **Histogenesis of Adenomas of the Parathyroid Gland.** (Rus) Lebkova, N. P. (Central Inst. Advanced Medical Training for Physicians, Moscow, USSR); Uranova, E. V. *Arkh Patol* 40(5): 9-25; 1978.

The similarity of adenomas of the parathyroid gland with other tumors of the APUD (amine precursor uptake and decarboxylation) system was investigated. The ultrastructural characteristics and the histology of 10 tumors were compared. Various histological variants of these tumors were shown to have a similar ultrastructure. The tumor tissue was made up of clear transitional cells and dark cells whose cytoplasm contained osmiophilic granules, filaments, laminar structures resembling Nissl bodies, fine granular and fibrous substances, and lipid inclusions. The adenomas were structurally similar to other endocrine-active tumors developing from cells of neuroectodermal origin (carcinoids, paragangliomas, etc). It is suggested that parathyroid gland adenomas belong to the APUD system. (21 refs)

78-4663 **Agglutinability, Cytoskeleton, and Surface Topography of Normal, Preneoplastic, and Neoplastic Mouse Mammary Cells In Vitro (Meeting Abstract).** (Eng) Asch, B. B. (Dept. Cell Biology, Baylor Coll. Medicine, Houston, TX, 77030); Brower, M. E.; Brinkley, B. R. *Proc Am Assoc Cancer Res* 19: 67; 1978. (no refs)

78-4664 **Occurrence and Preneoplastic Significance of Ductal Dysplasia in the Normal Mammary Tissue of the Strain GR Mouse (Meeting Abstract).** (Eng) Miyamoto, M. J. (Cancer Res. Lab., Univ. Calif., Berkeley, CA, 94720); DeOme, K. B.; Osborn, R. C. *Proc Am Assoc Cancer Res* 19: 32; 1978. (no refs)

78-4665 **The Incidence of Mammary Tumours in a Group of 40 8-Year-Old Female Beagle Dogs Used in a Toxicity Study.** (Eng) Wadsworth, P. F. (Huntingdon Res. Centre, Huntingdon, Cambridgeshire, England); Heywood, R.; Prentice, D. E.; Van Abbe, N. J. *Toxicol Lett* 1(5/6): 285-289; 1978.

The incidence of mammary tumors was determined in 40 purebred, nulliparous, 8-yr-old beagle dogs (Appleton strain) that had been used in a 7.5-yr toxicity study of chloroform in toothpaste. Since the treatment did not increase the incidence of mammary tumors, data from treated and control dogs were combined. Periodic clinical examination during this time revealed four palpable mammary gland abnormalities. After macroscopic and histological evaluation, two benign mammary tumors, a pericanalicular fibroadenoma and a papillary cystadenoma, a papillary complex cyst, and a fibroma were identified. Histological examination of the mammary glands from all dogs indicated an intracanalicular fibroadenoma, a complex adenoma, and a tubular adenoma in addition to the four palpable tumors. The incidence of benign mammary tumors was thus 7.5%. Furthermore, 11 areas of nodular hyperplasia were found in 9 dogs, and foci of epitheliosis were found in 35 mammary glands in 12 dogs. It is concluded that (1) malignant mammary tumors are uncommon in these dogs, (2) benign mammary tumors are present in only a small percentage of these dogs, and (3) mammary gland dysplasia is very frequent in these dogs. (12 refs)

78-4666 **Lobular Neoplasia (So-called Lobular Carcinoma In Situ) of the Breast.** (Eng) Haagensen, C. D. (Columbia Univ. Coll. Physicians and Surgeons, 630 W. 168th St., New York, NY, 10032); Lane, N.; Lattes, R.; Bodian, C. *Cancer* 42(2): 737-769; 1978.

A total of 211 cases of lobular neoplasia of the breast (lobular proliferation without coexisting infiltrating carcinoma) were identified among 5,560 benign epithelial mammary lesions diagnosed in one laboratory between 1930 and 1972. Of the 211 patients, who followed for a mean time of 14 yr, 190 were premenopausal at the time of diagnosis and 21 were postmenopausal. After menopause, the lobular phase of the neoplasia was considerably diminished and the ductal phase sharply increased. The left breast was slightly more affected (57%) than the right (43%). The lobular neoplasia was associated with gross cysts (≥3 mm in diameter) in 153 patients and benign palpable tumors in another 42. Of 209 patients (1 lost to follow-up and another excluded because of carcinoma prior to the neoplasia), 35 subsequently developed breast carcinoma compared with 4.85 expected. The risk of subsequently developing carcinoma appeared to increase up to 25 yr after the original diagnosis. In patients who subsequently developed carcinoma, half of the carcinomas were entirely or partially small cell, and another nine were intraductal. Study of the factors that predispose to breast carcinoma (history of the disease in a mother or sister, gross cystic disease, and lobular neoplasia) in the 209 patients indicated that these three factors predispose to cancer development in a cumulative manner. Findings from previous studies on lobular neoplasia are reviewed, as is the histological basis for the classification of this neoplasm. (20 refs.)

78-4667 **Anovulation and Increased Androgenic Activity as Breast Cancer Risk in Women with Fibrocystic Disease of the Breast.** (Eng) Grattarola, R. (Hormone Res. Lab., Istituto Nazionale dei Tumori, Via Venezian 1, Milan, Italy). *Cancer Res* 38(9): 3051-3054; 1978.

The androgenic activity of 26 women with fibrocystic disease of the breast was investigated to determine whether this activity is a factor in the hormonal etiology of breast cancer. Urine samples (24-hr) were collected on days 20-22 of the menstrual cycle and assayed by gas chromatography for testosterone and for androstanediol (5α-androstane-3α,17β-diol), the major metabolite of dihydrotestosterone. The mean values for both androgens were significantly higher in these women than in 18 normal women in the same age range. Samples of endometrium taken on the same days indicate that only 9/26 women had normal progestational patterns 16 had a hyperplastic pattern and 1 showed a simple proliferative pattern. Since the endometrial specimens were obtaine in the premenstrual period, the presence of hyperplasi proved that the menstrual cycle in over two-thirds of th patients was nonovulatory. This study shows that patient with fibrocystic disease have the same hormonal status a breast cancer patients, ie, anovulatory menstrual cycle, increased androgenic activity, and endometrial hyperplasia. 78-4669 Epidemiology of C57BL/6M Mice: Actuarial Data for a Control Population. (Fre) Mewissen, J. D. (Laboratoire de Radiobiologie, Universite Libre de Bruxelles, 109, boulevard de Waterloo, 1000 Brussels, Belgium); Rust, J. H.; Haren, J.; Clutin, M. J. *C R Soc Biol (Paris)* 171(5): 1140-1144; 1977.

An actuarial analysis of the causes of death, tumor incidence, and tumor/host index in 503 male and 497 female control C57BL/6M mice is presented. The animals were kept under controlled, hygienic conditions. The overall spontaneous tumor incidence was found to be 66.7% in males and 84.4% in females over the max life-span of 1,300 days. The age-adjusted Gompertzian incidence rates were found to be nonlinear. For males, the tumor/host index had two maxima at 650-700 days (1.35) and 850-900 days (1.3). The Gompertzian regression curves showed three incidence peaks, the first between days 350 and 400 due to the relative max of lymphoid lymphosarcoma, the second between days 650 and 700 due to the relative peak of histiocytic reticulum-cell sarcoma, and a third between days 850 and 900 due to the relative max of histiocytic reticulum-cell sarcoma and reticulocytic reticulum-cell sarcoma. The tumor/host index had two peaks for the females, one between days 800 and 850 (1.62) and a second between days 950 and 1,000 (1.6). The Gompertzian regression curves showed two peaks in the respective age brackets of 300-350 days and 800-850 days. The first was due to the relative max of lymphoid lymphosarcoma, the second to reticulocytic reticulum-cell sarcoma. (5 refs)

78-4670 Neurofibromatosis and Childhood Leukemia. (Eng) Bader, J. L. (Clinical Epidemiology Branch, NCI, A-521, Landow Building, Bethesda, MD); Miller, R. W. *J Pediatr* 92(6): 925-929; 1978.

Twelve new cases of childhood leukemia and neurofibromatosis (NF) were evaluated in conjunction with 17 previously documented cases. Among all 29 patients, 9 had acute ymphocytic leukemia (ALL), 8 had acute myelomonocytic eukemia (AMML), 8 had chronic myelogenous leukemia, 3 had acute myelogenous leukemia, and 1 had acute nonlymphocytic leukemia, type unspecified. There were 18 boys and 11 girls, all Caucasian, and 2 AMML patients were siblings. No consistent cytogenetic abnormalities were found in eight patients studied. NF was present in 70% of the patients, compared with the usual 50% observed in NF patients. All pa- ients with leukemia diagnosed at <2 yr of age had familial NF. Familial NF was present in 83% of patients with non- ymphocytic leukemia and in only 44% of patients with ALL. The ratio of ALL:nonlymphocytic leukemia among patients with sporadic NF was 5:3, compared with the 4:1 ratio observed for childhood leukemia in general. The ratio was 4:15 among patients with familial NF. For all cases combined, the ratio was 9:20. Two possible variants of the NF-leukemia association were NF with 'transient leukemia' and nonlymphocytic leukemia with multiple skin xanthomas and normal cholesterol levels. Abnormal radiologic findings occasionally associated with therapy in childhood leukemia were observed unusually early in one patient, possibly because of the presence of NF. The addition of NF to the array of genetic diseases and environmental factors associated with leukemia may help to explain the genesis of the neoplasm. (28 refs.)

78-4671 Occupational Exposure to Petroleum Products in Men with Acute Non-lymphocytic Leukaemia. (Eng) Brandt, L. (Dept. Internal Medicine, Univ. Hosp., S-221 85 Lund, Sweden); Nilsson, P. G.; Mitelman, F. *Br Med J* 1(6112): 553; 1978.

Occupational exposure to petroleum products was investigated in 50 men (aged 20-65 yr) with acute nonlymphocytic leukemia (ANLL) and in three groups of controls: 100 men (aged 20-65 yr) treated for nonmalignant disorders; 100 men (aged 20-65 yr) treated for allergic diseases; and 22 men (aged 20-62 yr) with chronic myeloid leukemia (CML) and 10 men (aged 41-63 yr) with chronic lymphocytic leukemia (CLL). Eighteen of 50 ANLL patients were occupationally exposed to petroleum products or their combustion residues. In each of the first two control groups, 10/100 patients were so exposed; 3/22 CML patients and none of the CLL patients were occupationally exposed to petroleum products. It is concluded that occupational exposure to motor fuel is unduly common in ANLL patients and that some leukemogenic factor may be present. (5 refs)

78-4672 Some Clues to Human Leukemia Expression from Comparison of Age-Standardized Incidence Rate Data in Man, Cat and Dog. (Eng) Schneider, R. (Animal Registry, Dept. Epidemiology and Preventive Medicine, Univ. California, Davis, CA, 95616). *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 37-40; 1978.

The incidence rate patterns of leukemias-lymphomas in cats, dogs, and humans were compared with the use of population-based animals and human tumor registries functioning in the same area of California. Incidence rates for dogs and cats were calculated using cases diagnosed from July 1967 to June 1974, and population estimates were obtained by survey for the middle of the case-collecting period. Incidence rates for humans were calculated using the leukemia and lymphoma cases reported in the San Francisco-Oakland Standard Metropolitan Statistical Area during 1969-1971. The leukemia female/male ratios were 0.6 for humans and cats and 1.1 for dogs, and the male/female ratios for all other cancers were 0.9 for humans, 1.0 for cats, and 1.3 for dogs. The dog did not show a consistent pattern of changing leukemia male/female ratios according to age, whereas the sex ratio changed with age according to a similar pattern in humans and cats. Both humans and cats showed a bimodal age-specific leukemia incidence rate that was not seen in dogs. The early peak for Hodgkin's disease in humans was at 20-29 yr and the early peak for leukemia in cats was at an equivalent age. The incidence of leukemia in dogs increased with increasing size of the dog, from about 10-15/100,000 for breeds < 10 kg to about 150/100,000 for the Great Dane and St. Bernard. Rates of all other cancers combined also increased with size, but to a lesser extent (one-half). This may be due to differences in rate of growth among breeds. The data indicate that of the three species, the dog may be the most efficient in protecting itself against these diseases and the cat the least efficient. (6 refs.)

78-4673 **The Effect of Neonatal BCG Vaccination on the Incidence of Leukemia.** (Ger) Ambrosch, F. (Institut fur Spezifische Prophylaxe und Tropenmedizin, Universitat Wien, Kinderspitalgasse 15, A-1095 Vienna, Austria); Krepler, P.; Wiedermann, G. *Munch Med Wochenschr* 120(8): 243-246; 1978.

Data from a literature review as well as current investigations were analyzed with respect to the possible nonspecific influence of BCG vaccinations on leukemia. Data from the five largest provinces of Austria indicate an inverse correlation between leukemia mortality and neonatal BCG vaccination. A protection rate of 0.88 for the prevention of leukemia deaths was calculated for the age group 0-5 yr; this corresponded to the literature protection rate of 0.85. Further analysis of the data indicated a deficit in positive tuberculin reactions at the onset of the disease in BCG-vaccinated children. A mathematical model was designed in order to calculate the frequency of positive tuberculin reactions in a population of 16 BCG-vaccinated leukemic children (ages 1-5 yr). There were only five positive tuberculin reactions, a finding that indicated a hypothetical influence of BCG vaccination on leukemia. (12 refs.)

78-4674 **Epidemiologic and Histologic Patterns of Hodgkin's Disease in Blacks.** (Eng) Vianna, N. J. (Cancer Control Bureau, New York State Dept. Health, Empire State Plaza, Tower Building, Room 523, Albany, NY 12237); Thind, I. S.; Louria, D. B.; Polan, A.; Kirmss, V.; Davies, J. N. *Cancer* 40(6): 3133-3139; 1977.

The epidemiologic, social, and histologic patterns of Hodgkin's disease (HD) in blacks were examined in Newark, New Jersey, and New York State (excluding New York City). The number of HD deaths among the Newark blacks was significantly smaller than expected for the young adult and older age groups. The number of deaths in the childhood age group was too small for statistical evaluation. In New York, a similar pattern was observed for the adult age groups, but the number of cases in children < 14 yr was greater than expected. The relative risk ratios of blacks to whites was 0.2 in Newark and 0.6 in New York. There was a general male predominance in both races, especially in blacks. A significantly greater number of black patients belonged to low-income groups. A comparison of these findings with those for blacks in Southern Transvaal, South Africa, and other countries suggests that the natural history of HD might be strongly influenced by social milieu. Age-related environmental factors might be important in the histologic reactivity of the host. (15 refs.)

78-4675 **Incidence of Hematological Neoplasms among Physicians.** (Eng) Gil-Extremera, B. (Dept. Developmental Therapeutics, Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., Houston, TX, 77025); Rodriguez, V.; Bodey, G. P. *Rev Esp Oncol* 24(1): 207-213; 1977.

The incidence of hematologic malignancies (acute leukemia, lymphoma, Hodgkin's disease, and multiple myeloma) among physicians was reviewed in a retrospective study covering 1969-1974. During this period, 435 physicians died of hematologic malignancies, an incidence of 2%, which was constant over the 6-yr period. No significant difference was detected in the distribution of deaths due to leukemia, lymphoma, Hodgkin's disease, or myeloma among the various specialty groups. Comparison of the mortality incidence of the physicans with that of the general population indicated that there was a higher incidence of death from acute leukemia among the physicans than among the general population. The difference in the number of deaths due to other hematological malignancies among physicans and the general population was not significant during 1969 and 1970. However, an increased number of deaths due to these diseases was observed among physicians in 1971, 1972, and 1974. Prospective studies should be undertaken to determine whether populations of physicians, such as oncologists, who are frequently exposed to these diseases are especially likely to contract them. (9 refs)

78-4676 **A Cluster of Hodgkin's Disease in a Small Community. Evidence for Environmental Factors.**

(Eng) Schwartz, R. S. (Dept. Internal Medicine, Univ. Michigan Medical Center, Ann Arbor, MI, 48104); Callen, J. P.; Silva, J. *Am J Epidemiol* 108(1): 19-26; 1978.

A cluster of Hodgkin's disease (HD) cases occurred in a small rural central Michigan town of 1,250 people. Ten cases of HD and three cases of non-Hodgkin's lymphoma were identified within or linked to this town since 1954. Therefore, this town had an av annual incidence and mortality for HD of 29.3 and 16.7 cases per 100,00 population respectively. Most HD cases demonstrated case-contact associations and a distinct geographic distribution. The data suggest that an environmental agent was responsible for the elevated rates of HD. One unique aspect of this cluster is that the town has only one industry, a large grain elevator. The cases closely surrounded this elevator. It is postulated that the residents are subject to chronic immune stimulation from mitogenic substances in the local environment. These agents may alter the immunity in the residents and predispose them to HD. (40 refs.)

78-4677 **Pesticides and Lymphoma in Iowa.** (Eng) DeKraay, W. H. (Ottumwa, IA). *J Iowa Med Soc* 68(2): 50-53; 1978.

Iowa counties with higher than expected lymphoma incidences were clustered along the Des Moines and Nishnabotna Rivers. Water samples from these and other rivers indicated seasonal dieldrin concentrations as high as 65 parts per trillion. The lowest dieldrin concentrations were found in the drinking water of cities that obtained water from wells, and these cities did not have high lymphoma rates. Dieldrin levels in catfish (toxic level established at 300 ppb) ranged as high as 1,600 ppb in some rivers, but no attempt was made to determine catfish consumption by lymphoma patients. A study of 110 lymphoma patients in one county revealed that most were 60-80 yr old. Approx 34% had Hodgkin's, 66% non-Hodgkin's lymphoma. The age pattern of Hodgkin's disease did not follow the bimodal curve expected in the third and sixth decades. A 5-yr survival rate of 29% and a 5-yr recurrence-free rate of 15% were observed. With the banning of dieldrin in 1974, a follow-up study of lymphoma incidence will be of interest. (6 refs.)

78-4681 **Risk Factors of Breast Cancer in Burma.** (Eng) Hlaing, T. (Epidemiology Div., Dept. Medical Res., Ministry Health, Zafar Shar Road, Dagon P.O., Rangoon, Burma); Myint, T. M. *Int J Cancer* 21(4): 432-437; 1978.

A hospital-based case-control study of breast cancer was conducted in Rangoon, Burma. One hundred ninety-three breast cancer cases and 403 controls were interviewed. The median age of the breast cancer patients was 52.1 yr, and that of the controls was 50.4 yr. The risk of breast cancer was significantly increased among more educated women ($p = 0.0003$) and among women who had their menopause after the age of 47 ($p = 0.00003$). It was also increased in women who had their menarche prior to age 15. There was no association between risk and lactation. A strong inverse relation was found between risk and parity: women who had six or more children had only one-third the risk of cancer of married women who had less than four children. Risk was increased in women aged >30 yr at first birth. The age-standardized incidence of breast cancer in Rangoon, 25.1/100,000 women-years, is higher than that of other Asian populations and lower than that in North America and northern Europe. The predomination of parity rather than age at first birth as a risk factor in Rangoon is unique and should be explored further. (18 refs)

78-4682 **Cell Kinetics of Large Cell Lung Tumors and Protocol Design (Meeting Abstract).** (Eng) Jacob, H. E. (Allegheny General Hosp., Pittsburgh, PA, 15212); Braunschweiger, P. C.; Stragand, J. J.; Novak, J.; Schiffer, L. M. *Proc Am Assoc Cancer Res* 19: 397; 1978. (no refs)

78-4683 **The Prevalence of Sjogren's Syndrome in Non-Hodgkin's Lymphoma. (Meeting Abstract).** (Eng) Pritchard, K. I. (Ontario Cancer Inst. M4X 1K9, Univ. 78-4684 **Ethnic-related Incidence of Ovarian Carcinoma in New York City.** (Eng) Soichet, S. (New York Hosp.-Cornell Medical Center, New York, NY). *Isr J Med Sci* 14(3): 363-369; 1978.

A two-part statistical study of ovarian cancer incidence in New York City was conducted in an effort to explain the striking racial differences in mortality from this disease. In the first part, an examination of 874 death certificates from case reports for 1964 (487) and 1974 (387) revealed (1) a lower incidence of ovarian cancer among nonwhite than among white women and (2) a higher incidence among Jewish than among non-Jewish women. For Jewish women, the mortality from ovarian cancer was similar in 1964 and 1974. The second part entailed a review of 143 records from New York City hospitals from which more precise data, such as history and treatment, were available. Clinical features related to the different ethnic and racial incidences were analyzed, but no etiologic factors could be correlated with the disease. (23 refs)

78-4685 **Cohort Mortality for Prostatic Cancer among United States Nonwhites.** (Eng) Ernster, V. L. (Dept. Biomedical and Environmental Health Sciences, Univ. California, Berkeley, CA, 94720); Selvin, S.; Winkelstein, W. *Science* 200(4346): 1165-1166; 1978.

To determine if a cohort or a generational effect is wholly or partially responsible for the increase in prostatic cancer mortality among blacks, prostatic cancer mortality rates among men aged 45-84 yr were analyzed for separate birth cohorts of US nonwhites extending from 1846 to 1925. Since blacks make up the majority of nonwhites, only small effects could be due to other nonwhites. Rates for all ages peaked in the 1896-1900 in the cohort and declined thereafter, at least for men under the age of 70 for whom data were available. This presages an arrest and reversal of the time trend in summary mortality rates as more recent nonwhite cohorts reach the ages of max risk. Research into the historical experience of the 1896-1900 and earlier nonwhite birth cohorts may provide clues to agents associated with prostatic cancer. (7 refs)

78-4686 **Association of Colo-Rectal and Prostatic Cancer (Meeting Abstract).** (Eng) Paladine, W. J. (Oncology Section, Albany Veterans Admin. Hosp., Albany, NY, 12208); Chalmers, P. *Proc Am Assoc Cancer Res* 19: 340; 1978. (1 ref)

78-4687 **Fecal Microbial Flora in Seventh Day Adventist Populations and Control Subjects.** (Eng) Finegold, S. M. (Infectious Disease Section, Wadsworth Hosp. Center, Veterans Admin., Los Angeles, CA 90073); Sutter V. L.; Sugihara, P. T.; Elder, H. A.; Lehmann, S. M.; Phillips R. L. *Am J Clin Nutr* 30(11): 1781-1792; 1977.

The fecal microbial flora content of vegetarian Seventh Da Adventists was investigated and compared to nonvegetaria Adventists, non-Adventists on a conventional American diet Japanese-Americans on either a Western or Japanese diet and Caucasians on a conventional American diet. Ther was little difference among the Adventist groups. Group at high risk for colon cancer (Japanese-Americans o Western diet and Caucasians on conventional Americar diet) had significant differences as compared to lo risk populations (Japanese-Americans on Japanese die and Adventists). (22 refs.)

78-4688 **Further Biologic Characteristics of a Huma Carcinoembryonic Antigen-producing Colon Carcinoma Cell Line.** (Eng) Drewinko, B. (Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., 6723 Bertner Ave., Houston, TX, 77030); Yang, L. Y.; Barlogie, B.; Romsdahl, M.; Meistrich, M.; Malahy, M. A.; Giovanella, B. *J Natl Cancer Inst* 61(1): 75-83; 1978.

Human carcinoembryonic antigen (CEA)-producing colon adenocarcinoma cells (LoVo cells) grown in vitro were characterized in terms of several kinetic and biological parameters. Doubling times of exponentially growing cells ranged from 34 to 38 hr for initial cell concentrations of 10^5 to 7 x 10^5/petri dish. The generation time was 29.3 hr. Cultures exposed continuously to tritiated thymidine had a growth fraction of 90%. Compartment distribution calculated in reference to cell cycle transit times measured by pulse-labeled mitosis techniques was similar to that defined directly by pulse cytophotometry (PCP). PCP analysis of cells in the stationary growth phase revealed a significant fraction of cells with S-phase DNA content (15%), even though the simultaneously defined labeling index was only 1%. Adequate synchronization in the S- and G_2-phases was achieved by treating the cells with 7 mM thymidine for 24 hr. Centrifugal elutriation and mitotic selection were inferior in terms of reproducibility and cell yield. Colony formation was most efficient for cells plated in fresh medium and incubated for 2 days. The tumorigenic potential of LoVo cells wa established by their transplantation into nude mice Inoculated cells grew relatively slowly, and visibl tumor nodules appeared after 3 wk. The transplante cells retained the morphologic features of the origina tumor. Sera from three LoVo cell-bearing mice assayed for CEA when the animals were killed contained 31.3, 40.0, and 87.5 nanograms of CEA/mg, but no CEA was detected in control mice. The LoVo line may be a unique candidate for an in vitro model of colon carcinoma. (37 refs)

78-4689 **An Investigation of the Use of Asbestos Cemen Pipe for Public Water Supply and the Incidenc**

of Gastrointestinal Cancer in Connecticut, 1935-1973. (Eng) Harrington, J. M. (Environmental Hazards Activity, Chronic Diseases Div., Bureau Epidemiology, Center Disease Control, Atlanta, GA 30333); Craun, G. F.; Meigs, J. W.; Landrigan, P. J.; Flannery, J. T.; Woodhull, R. S. *Am J Epidemiol* 107(2): 96-103; 1978.

Determination was made of the effects of the use of asbestos cement pipe for public water supply on the incidence of stomach, colon, and rectal cancer in Connecticut between 1935 and 1973. Tumor incidence per township was obtained from the Connecticut Tumor Registry. For all towns, the date(s) of installation of the asbestos cement pipe, the length of this type of pipe compared to other types, and the population serviced by the pipe were determined. These factors were incorporated into two composite indices: the Assessment of Exposure and Risk Factors. Observed to expected (O/E) ratios of all three types of cancer tended to increase as the population density increased. Furthermore, O/E ratios for colon and rectal cancer were opposite those for stomach cancer. However, there was no pattern of association between cancer incidence and the use of asbestos cement pipe. (26 refs)

78-4690 **An Occupational Group with a High Risk of Large Bowel Cancer.** (Eng) Vobecky, J. (Faculte de Medicine, Universite de Sherbrooke, Sherbrooke, Quebec, Canada J1H 5N4); Devroede, G.; Lacaille, J.; Watier, A. *Gastroenterology* 75(2): 221-223; 1978.

Over a 1.5-yr period, five individuals employed in the same unit of a carpet factory that manufactured synthetic threads developed large bowel cancer. Workers stated that there was a strong odor in this unit while a powdery ingredient was being liquefied to produce the material. The tumors were of similar histological type, the patients were 31-58 yr, and there was no family history of cancer. Duration of exposure ranged from 10 to 32 yr. A detailed study of the occurrence of colorectal cancer in the area from 1965 to 1975 was undertaken to determine if this outbreak of cancer was a chance occurrence or the result of occupational exposure. Review of 1,000 medical records of patients with colorectal cancer revealed that 30 patients had been employed in the carpet factory. Further analysis was restricted to 12 men whose cancers occurred from 1971 to 1975 and who were working in the factory at the time of diagnosis. Most cancers were in the left colon, and the most frequent histopathological type was adenocarcinoma. The observed age- and sex-adjusted relative risk ratio was 10 times higher among workers in the carpet factory than among workers in other occupations. The morbidity in the studied group was 11.4 times higher than the expected one. (18 refs.)

78-4691 **Fecal Constituents of a High-Risk North American and a Low-Risk Finnish Population for the Development of Large Bowel Cancer.** (Eng) Reddy, B. S. (Naylor Dana Inst. Disease Prevention, American Health Foundation, Valhalla, NY, 10595); Hedges, A.; Laakso, K.; Wynder, E. L. *Cancer Lett* 4(4): 217-222; 1978.

Feces were collected from age-matched, healthy, middle-aged male volunteers in Kuopio, Finland (a low-risk population for the development of colon cancer), and the New York metropolitan area (a high risk population for colon cancer), and their constituents were compared. The av daily intake of fat and protein was essentially the same in the two populations, but the intake of carbohydrate was higher in Kuopio. The main sources of the fat were from meat in New York, from dairy products in Kuopio. The latter group also had a higher intake of fish, whole-rye bread, and whole-grain cereals. The number of stools passed per day was higher in Kuopio; the percentage of dry matter was lower, but the daily stool output was three times higher. Fecal bacterial β-glucuronidase activity per gram of dry feces was lower in Kuopio, but there was no difference in the daily output of enzyme activity between the two groups. A significantly lower concentration of secondary bile acids was found in Kuopio, but the total daily output of these bile acids was the same in the two groups. There was no difference in the concentration of neutral sterols, but the daily excretion of neutral sterols was higher in Kuopio. These findings suggest that the greater fecal bulk in Kuopio may dilute tumorigenic compounds, and tumor promotors (in the bile acids) that come in direct contact with the colonic mucosa. (26 refs)

78-4692 **Colo-rectal Carcinoma in Young Adults.** (Eng) Koyama, Y. (Dept. Surgery, Natl. Cancer Center Hosp., 5-1-1, Tsukiji, Chuo-ku, Tokyo 104, Japan); Hojo, K.; Hirota, T.; Kodaira, S. *Jpn J Clin Oncol* 8(1): 21-26; 1978.

Twenty-five patients <29 yr old (Group 1) and 693 patients >30 yr old (Group 2), all with carcinoma of the large intestine, were compared to determine if there are any factors connected with the etiology and prognosis in young patients. Localized lesions were found in 9 Group 1 patients, and 6 had distant metastases at the time of surgery; 19 underwent curative resection. Study of the crude cumulative survival rate indicated that only 37% of the Group 1 patients survived 5 yr, compared with 56% of the Group 2 patients. Histologically, the mucinous type of tumor, especially signet ring cell carcinoma was observed more frequently in Group 1 than in Group 2. Cancer cells permeating into the lymph vessels were found in most of the Group 1 patients. A comparison of the frequencies of coincidental cancerous and/or precancerous lesions at the time of surgery indicated that synchronous multiple cancers were present in 3/23 young patients treated by resection compared with 22/677 older patients; this difference was statistically significant. The incidence of familial polyposis coli, which accompanied invasive carcinoma, was also significantly higher in the younger patients. The cumulative no evidence of disease rate after curative surgery was lowest among Group 1 patients; it increased stepwise with each successive decade. (20 refs.)

78-4693 **Topographic Study of Glycoconjugates in Proximal and Distal Rat Colonic Mucosa (Meeting Abstract).** (Eng) Freeman, H. J. (Veterans Admin. Hosp., Univ. California, San Francisco, CA); Kim, Y. S.; Lotan, R. *Clin Res* 26(3): 319A; 1978. (no refs)

78-4694 **Spectrum of Fecal Bacterial Flora in Colon and Non-Gastrointestinal Cancer Subjects (Meeting Abstract).** (Eng) Floch, M. H. (Norwalk Hosp., Norwalk, CT); Moskovitz, M.; Vargo, D.; Ramos, R.; May, S.; Fuchs, H. M. *Clin Res* 26(3): 318A; 1978. (no refs)

78-4695 **Statistical Studies in the Aetiology of Malignant Neoplasms. V. Trends and Risks. Denmark 1943-72.** (Eng) Clemmesen, J. (Cancerregisteret, Finsen Inst., Strandboulevard 49, Copenhagen 2100, Denmark). *Acta Pathol Microbiol Scand [A]* (Suppl. 261): 1-286; 1977.

Statistical studies on malignant neoplasms in humans are compiled using data obtained from the Danish Cancer Registry. In Denmark, there was a gradual increase in cervical carcoma from 1943 to 1967, followed by a decrease from 1968 to 1972. In Connecticut, however, a steady decrease in incidence was noted. In both areas, an increase in the number of in situ cancers was accompanied by a decrease in invasive cancers. Endometrial carcinomas in Denmark have increased with time. Clinical data on 8,078 patients treated with phenobarbital and followed until their death failed to reveal any carcinogenic effects. Data from air pollution studies indicate that pollution may play an etiological role in lung cancer, but the absence of data on local smoking habits makes any definite conclusions difficult. Gastric cancer incidence decreased from 1943 to 1972, although some of this decrease could be attributed to more effective diagnostic assessment of a previously overrated diagnosis. A study of the survival of breast cancer patients revealed that the 7-yr survival for women $<$ 45 yr old improved between 1949 and 1954; the improvement was less marked in women $>$ 45 yr old. However, morbidity changed little between 1950 and 1970 for women $<$ 45 yr old, and it increased for women $>$ 45 yr old. Tables of morbidity rates for various malignant neoplasms for the years 1943-1972 are also presented. (50 refs)

78-4696 **Incidence of Endometrial Carcinoma in King County, Washington: A Standardized Histologic Review: Brief Communication.** (Eng) Szekely, D. R. (Dept. Epidemiology, SC-36, Sch. Public Health and Community Medicine, Univ. Washington, Seattle, WA, 98195); Weiss, N. S.; Schweid, A. I. *J Natl Cancer Inst* 60(5): 985-989; 1978.

A total of 150 endometrial cancer specimens from women aged 35-74 yr who were residents of King County, Washington, during the first 6 mo of 1975 were reviewed by on
pathologist who used uniform criteria to assess the cance
The routinely reported incidence of this tumor was judge
to be inflated, falling from 108.2 to 88.5/100,000 women afte
the exclusion of cases found not to be unequivocally mali
nant. Nonetheless, this rate represented a large increase ove
the rate of 47.3/100,000 observed in the US Third Nationa
Cancer Survey 5 yr previously. The proportion of wome
who used noncontraceptive estrogen preparations for a mini
mum of 2 yr varied between 70% and 81% for any grade c
cancer. More women with cancer confined to the endometri
um were estrogen users than were women with cancer pen
trating into the myometrium. (14 refs)

78-4697 **Epidemiology and Pathophysiology of Corp**
Carcinoma. (Eng) Kjellgren, O. (Dep
Gynaecological Oncology, Univ. Umea, S-901 85 Ume
Sweden). *Acta Obstet Gynecol Scand [Suppl]* (65
77-82; 1977.

The incidence of endometrial carcinoma in Sweden is re
viewed. Between 700 and 800 new cases are being reporte
annually for an incidence of approx 19/100,000; th
death rate from endometrial carcinoma accounts fo
0.5% of all female deaths. Most cases occur between th
ages of 50 and 70 yr. Many of these patients are ove
weight, and comparison with a control population i
dicated that the former are approx 13% heavier tha
the latter. A person who is 21 to 50 pounds overweig
between the ages of 25 and 29 has a risk factor c
approx 3; being 50 pounds overweight carries a ris
factor of 10. Late menopause, nulliparity, uterine f
broids, and diabetes are frequent in endometrial carcinom
patients. A review of the experimental evidence linking estro
gens with cancer indicated that cancer can only be induce
in animal strains with a high spontaneous rate of cancer an
under certain circumstances. Although endometrial cance
can be induced in about 8% of the patients with gonada
dysgenesis, this induction results from diethylstilbestrol an
not steroids. The literature contains controversial results:
is not known whether changes in the uterus following estro
gen treatment are really cancerous or just a hyperstimulatio
of the endometrium. (22 refs.)

78-4698 **Relationship Between Epidemiologic and Endo**
crinologic Aspects of Cervical Cancer. (Eng
Kodama, M. (Lab. Chemotherapy, Aichi Cancer Center Re
Inst., Chikusa-ku, Nagoya, Japan); Kodama, T.; Totani, R
Aoki, K. *J Natl Cancer Inst* 61(1): 35-39; 1978.

Epidemiologic and endocrinologic data were used to dete
mine the etiologic relevancy of steroid deviations in the urin
of cervical cancer patients. It was found that th
premenopausal cervical cancer patient had her first child a
a significantly earlier age than did an age-matched urban con

rol, despite their similar ages at menarche. However, when he same patient was compared with a premenopausal rural ontrol, this difference was not found. The same parameter lso failed to differentiate a postmenopausal patient from a orresponding urban control. The premenopausal patient vho was indistinguishable from the rural control by age at irst delivery was, however, distinguished from the rural conrol by reduced excretions of adrenal steroids, including 1-deoxy-17-ketosteroids and some corticosteroid metaboites. The spectrum and degree of deviation of urinary steoids for the cervical cancer patient coincided with the specrum and degree of age dependency of the urinary steroids or a normal woman during and after adolescence. These indings indicate that the inability of the reproductive parameter to discriminate a cervical cancer patient rom a rural control was associated with growth retardaion in a population and that a maturation deficiency of the adrenal gland (arrest of adrenarche) is implicated n the genesis of cervical cancer. (10 refs)

8-4699 **Carcinoma of the Female Breast in Jamaica.** (Eng) Harris, M. (Dept. Pathology, Univ. Manchester, Manchester M13 9PT, England). *Trop Geogr Med* 29(3): 213-222; 1977.

The incidence of breast cancer in Jamaican women is intermediate between the low levels of African countries and the high levels of the US, Great Britain, and other Western industrial societies. The annual incidence in Jamaica has shown an upward trend from 1958 to 1974. Compared with Uganda, breast cancer in Jamaica conforms to a westernized pattern in terms of the age-specific incidence curves and tumor stage at presentation. However, there are no marked histologic differences among the breast cancers in Uganda, Jamaica, and the U.S. The Jamaican incidence is higher than expected in view of the fact that early first pregnancies (purported to have a protective effect) are common in this country. (20 refs.)

8-4700 **Barrier Contraceptive Practice and Male Infertility as Related Factors to Breast Cancer in Married Women.** (Eng) Gjorgov, A. N. (Dept. Res. Medicine, Dept. Obstetrics and Gynecology, Univ. Pennsylvania Sch. Medicine, Philadelphia, PA, 19104). *Med Hypotheses* 4(2): 79-88; 1978.

A case-control study of 153 consecutive mastectomy cases of married or never-married white women, 35-60 yr of age at diagnosis, and 168 controls was conducted to test the hypothesis that a reduced exposure to human seminal factors in early reproductive life is a risk factor in breast cancer. It was found that 71.2% of the breast cancer patients used barrier methods of contraception (condom, withdrawal, abstinence, celibacy) compared with 34.5% of the controls. Preliminary results indicate that the relative risk of exposure to the hypothetical semen-factor deficiency is 4.69 times greater for breast cancer patients than for controls, which suggests that barrier contraception and male infertility may play more than a chance role in this disease in married women. When contraceptive methods alone are taken into consideration, the relative risk is increased up to 5.3 times. These data also indicate that 16.1% of the women using barrier contraception would develop breast cancer compared with 3.4% of the women using nonbarrier techniques. Elimination of the barrier method of contraception would result in a >50% reduction in breast cancer incidence among married women. (36 refs)

78-4701 **Results of Case-Control Study of Breast Cancer.** (Eng) Krajinovic, S. (Inst. Epidemiology, Medical Faculty, Belgrade, Yugoslavia); Udicki, S.; Radovanovic, Z.; Merkas, Z.; Jankovic, S.; Miljkovic, V. *In: Characterization and Treatment of Human Tumours. Proceedings of the Seventh International Symposium on the Biological Characterization of Human Tumours held in Budapest, April 13-15, 1977.* Davis, W.; Harrap, K. R., eds. (Amsterdam: Excerpta Medica): Advances in Tumour Prevention, Detection and Characterization. Vol. 4, 332 pp.; 187-190; 1977.

Results of an interview of 447 women with breast cancer from hospitals in Belgrade, Hungary, and 447 age-matched controls revealed that the most significant difference between the two groups was the time between successive periods: the interval was much shorter in the cancer patients. In addition, the women with cancer were more often nulliparous, had later deliveries, fewer children, shorter duration of lactation, and a shorter duration of menstruation. (7 refs.)

78-4702 **The Possible Role of Hormones, Marital Status and Gestation in Breast Cancer.** (Eng) Juhasz, L. (Cancer Registry, Szabolcs-Szatmar County, Nyiregyhaza, Hungary). *In: Characterization and Treatment of Human Tumours. Proceedings of the Seventh International Symposium on the Biological Characterization of Human Tumours held in Budapest, April 13-15, 1977.* Davis, W.; Harrap, K. R., eds. (Amsterdam: Excerpta Medica): Advances in Tumour Prevention, Detection and Characterization. Vol. 4, 332 pp.; 191-193; 1978.

A retrospective analysis of data on 505 patients with breast cancer and 866 controls from two counties in East Hungary indicated that marriage, longer duration of marriage, greater number of deliveries, younger age at first birth, longer duration of lactation, and earlier menopause may be associated with a decreased risk of breast cancer. (2 refs.)

78-4703 **Breast Cancer in a Psychiatric Hospital Before and After the Introduction of Neuroleptic Agents (Meeting Abstract).** (Eng) Wagner, S. (Norristown State Hosp., Norristown, PA, 19401); Mantel, N. *Proc Am Assoc Cancer Res* 19: 180; 1978. (no refs)

78-4704 **Familial Breast Cancer: Risk to the Contralateral Breast.** (Eng) Harris, R. E. (Dept. Preventive Medicine and Public Health, Sch. Medicine, Creighton Univ., Omaha, NB, 68178); Lynch, H. T.; Guirgis, H. A. *J Natl Cancer Inst* 60(5): 955-960; 1978.

The pathology reports of 198 women with familial breast cancer were reviewed to determine the chronologic features of tumorigenesis in the breast contralateral to the site of the initial mastectomy. The actuarial data revealed two major risk periods with an intervening gap in which no malignant tumors of the contralateral breast were detected. The cumulative cancer risk to the contralateral breast increased annually at 2.8% in the first 6 postoperative yr, showed no increase in the next 7 yr, and finally increased at an annual rate of 6.8% between years 13 and 16. The corresponding annual rates of increase for second primary breast cancer in the two risk periods were 1.6% and 5.9%, respectively. A total of 37 patients manifested bilateral breast cancer, of whom 21 had pathologically confirmed second primary carcinomas. Of these patients, 27 exhibited a relatively short interval between mastectomies (1.7 yr), but 10 had a much longer disease-free interval (16.5 yr). It is suggested that tumors manifested in the contralateral breast within 6 yr of the initial breast cancer were already developing but were not clinically discernible at the time of the first mastectomy. The extended disease-free interval in many patients suggests that the host defense mechanisms may have been stimulated by the first tumor, which in turn had a persisting suppressive effect on de novo carcinogenesis in the contralateral breast. These findings indicate the need for vigorous cancer surveillance of long-term survivors of an initial breast cancer, particularly in familial patients. (12 refs)

78-4705 **Racial Trends in Urban Breast Cancer Incidence and Cancer Control (Meeting Abstract).** (Eng) Brennan, M. J. (Michigan Cancer Foundation, Detroit, MI, 48201); Wilt, G. M.; Albert, S. *Proc Am Assoc Cancer Res* 19: 391; 1978. (no refs)

78-4706 **Reproductive History and Risk of Breast Cancer. A Case-Control Study in an Unselected Swedish Population.** (Eng) Adami, H. O. (Dept. Surgery, Univ. Hosp., S-750 14 Uppsala, Sweden); Rimsten, A.; Stenkvist, B.; Vegelius, J. *Cancer* 41(2): 747-757; 1978.

The reproductive history of 179 women with breast cance and 179 age-matched controls was compared in an attemp to link this history with breast cancer risk. There was no significant difference between the two groups with respect to age at menarche, age at first birth, age at menopause, or number of children. Selection of the controls from the genera population and not from hospital patients could account for the differences between these findings and previous reports (46 refs)

78-4707 **Characteristic Species Dependent Growth Patterns of Mammalian Neoplasms.** (Eng) Brunton, G. F. (Dept. Clinical Physics and Bio-Engineering, West of Scotland Health Boards, 9-11 W. Graham St., Glasgow G4 9LF, Scotland); Wheldon, T. E. *Cell Tissue Kinet* 11(2) 161-175; 1978.

Data on tumor growth in mice, rats, and hamsters and on the growth of human multiple myeloma support the idea of a species-specific relation between two supposedly independent parameters in the Gompertz equations frequently used to quantify tumor growth curves. These findings support previous conjectures, based on observations of the growth kinetics of a murine melanoma and a rat mammary carcinoma, that such a relation may be a general feature of tumor growth. Data on the growth of xenografts of human colorectal tumors in immune-deprived mice suggest that the growth relation reflects the ability of a particular species to support a tumor of certain max size. The existence of this relation simplifies the task of predicting complete patterns of undisturbed neoplastic growth in these species. (20 refs)

78-4708 **The Contributions of Diet and Childbearing to Breast-Cancer Rates.** (Eng) Hems, G. (Dept. Community Medicine, Univ. Medical Buildings, Foresterhill, Aberdeen, Scotland). *Br J Cancer* 37(6): 974-982; 1978.

The 1970-1972 mean, age-standardized, breast cancer mortality rates for women of 41 countries, were closely correlated with dietary data for 1964-1966. Partial correlation analysis indicated that breast cancer rates were positively correlated with total fat, animal protein and animal calories, independently of other components of diet. These three components were correlated with one another so closely that it was not possible, with available data, to say whether any one was associated with breast cancer independently of the other two. In addition to, and independently of, these correlations, breast cancer was associated with consumption of refined sugar. In 26 countries, breast cancer mortality rates at 50-54 yr during 1964-1967 were closely correlated with childbearing, expressed as mean family size for women aged 45-49 yr in 1960-1961. However, this correlation was not independent of the correlations with diet, and it was concluded that variations of breast cancer rates among countries arose predominantly from differences in diet. The variation of breast cancer risk with childbearing, observed in clinical studies, seemed best regarded as a second gradient of risk, seen more readily as variation of breast cancer rates within a population, in which differences in diet would be relatively small. The physiological basis for the association between breast cancer and diet was not clear. The dietary associations did not correlate in an obvious way with height, obesity, and estrogen levels, factors observed in clinical studies to influence risk of breast cancer. That the observed statistical associations were real was supported by published findings on the effects of diet on mammary cancer in experimental animals, as well as the lower rates of breast cancer among vegetarians. (44 refs)

78-4709 **Incidence of Salivary Gland Tumours in Scotland: Accuracy of National Records.** (Eng) Lennox, B. (Dept. Pathology, Western Infirmary, Glasgow G11 6NT, Scotland); Clarke, J. A.; Drake, F.; Ewen, S. W. *Br Med J* 1(611): 687-689; 1978.

The accuracy of the Information Services Division files on the incidence of malignant and benign salivary gland tumors in Scotland was evaluated by comparing the files with case notes and pathology department records from selected hospitals. Because of miscoding of benign tumors as malignant, the true incidence of the two tumor types could not be ascertained. The study did indicate, however, that the incidence of all tumors of major salivary glands exceeds 40/million/yr. This incidence is higher than that in any other nationality except Canadian Eskimos. Analysis of pathology records indicated that eastern Scotland has an unusually high incidence and that the reported figures in other areas are likely to be too low. (8 refs)

78-4710 **Occupational Hazards to Reproduction and Health in Anaesthetists and Paediatricians.** (Eng) Rosenberg, P. H. (Dept. Anaesthesiology, Helsinki Univ. Central Hosp., SF-00290 Helsinki 29, Finland); Vanttinen, H. *Acta Anaesthesiol Scand* 22(3): 202-207; 1978.

The results of a questionnaire sent to Finnish anesthetists and pediatricians (controls) indicated that exposure to halothane anesthetic vapor in an operating room does not produce a higher risk of reproductive or teratogenic complications or malignancies compared with that in the control group. (19 refs)

78-4711 **Mesothelioma and Asbestos in the Province of Quebec, 1969-1972.** (Eng) Theriault, G. P. (Dept. Social and Preventive Medicine, Laval Univ., Quebec, Canada); Grand-Bois, L. *Arch Environ Health* 33(1): 15-19; 1978.

A retrospective case-control study of deaths from mesothelioma in the Province of Quebec during 1969-1972 was undertaken to determine the relationship between this tumor and industrial exposure to asbestos. Fifty-three confirmed cases and 15 doubtful cases of mesothelioma occurred during the study period. Most of the patients died between the ages of 40 and 70 yr, and the overall male-to-female ratio was 2 to 1, being especially high for pleural mesothelioma. The incidence was highest in urbanized areas. Among the 32 confirmed mesothelioma patients for whom occupational histories were obtained, 34.4% had histories of direct exposure to asbestos compared with only 1.6% in the control group. Exposure was related to processing in more cases than to mining. None of the women who died of mesothelioma had a history of direct occupational exposure. No relationship was found between cigarette consumption and mesothelioma. Chrysotile fibers, which are primarily associated with mining, appear to be less related to mesothelioma than other types of asbestos fibers, which are more involved in processing. (17 refs)

78-4712 **A Summary of Asbestos Fibre Counting Experience in Seven Countries.** (Eng) Gibbs, G. W. (Occupational Health and Safety Unit, McGill Univ., Montreal, Quebec, Canada); Baron, P.; Beckett, S. T.; Dillen, R.; du Toit, R. S.; Koponen, M.; Robock, K. *Ann Occup Hyg* 20(4): 321-332; 1978.

The membrane filter method for evaluating airborne concentrations of asbestos in the work place was evaluated in laboratories in Belgium, Canada, Finland, Germany, South Africa, the United Kingdom, and the United States. A comparison of the fiber counts in the different countries revealed large differences for single samples, but laboratories that were in close contact and regularly exchanged samples had better agreement of their results. Methods for improving the reproducibility of the counts are outlined. (9 refs)

78-4713 **A Cohort Study on Trichloroethylene Exposure and Cancer Mortality.** (Eng) Axelson, O. (Dept. Occupational Medicine, Regional Hosp., 701 85 Orebro, Sweden); Andersson, K.; Hogstedt, C.; Holmberg, B.; Molina, G.; de Verdier, A. *J Occup Med* 20(3): 194-196; 1978.

A cohort of 518 Swedish men exposed to trichloroethylene (TCE) was studied with respect to cancer mortality. The men were divided into high-/and low-exposure categories as estimated by the av trichloroacetic acid level in the urine: those with levels > 100 mg/liter were in the high exposure group, and those with levels < 100 mg/liter were in the low-exposure group. Requiring 10 yr of latency time after the date of first employment (assumed to correspond to the time of first exposure) resulted in 3,643 person-yr of observation. Subdividing the cohort with regard to 10 yr of latency time as to high-/and low-exposure categories resulted in 548 and

3,095 person-yr of observation, respectively. There was a close agreement between expected and observed number of cancer cases in both the high-/and low-exposure groups. No particular type of cancer was overrepresented, although there were two leukemias and two stomach cancers. Both the leukemia and stomach cancer cases were in the low-exposure category. It seems justified to consider TCE as a possible human carcinogen, but one that is not more potent than many other industrial compounds. There is probably no serious hazard at low exposures. (21 refs)

78-4714 **Association of Cancer Sites with Tobacco and Alcohol Consumption and Socioeconomic Status of Patients: Interview Study from the Third National Cancer Survey.** (Eng) Williams, R. R. (Dept. Internal Medicine, Univ. Utah Coll. Medicine, Salt Lake City, UT 84121); Horm, J. W. *J Natl Cancer Inst* 58(3): 525-547; 1977.

From personal interviews with 7,518 invasive cancer patients obtained in the Third National Cancer Survey, the quantitative lifetime use of cigarettes, cigars, pipes, unsmoked tobacco, wine, beer, hard liquor, and combined alcohol were recorded, as well as education and family income level. In an initial screening analysis of these data, Mantel-Haenszel 2 x 2 contingency tabulations and multiple regression analyses were used to compare each specific cancer site with controls from other sites to test for associations with exposure variables. Significant positive associations with cigarette smoking were found for cancers of the lung, larynx, oral cavity, esophagus, stomach, pancreas, bladder, kidney, and uterine cervix. Other forms of tobacco were associated with cancers of the oral cavity, larynx, lung, and cervix. Consumption of wine, beer, hard liquor, and all combined showed positive association with neoplasms of the oral cavity, larynx, esophagus, colon, rectum, breast, and thyroid gland. College education and high income showed positive associations with cancers of the breast, thyroid gland, uterine corpus, and melanomas in men. These indicators of high socioeconomic status showed inverse associations with invasive neoplasms of the uterine cervix, lung, lip-tongue, and colon in women. College attendance (but not income) showed an inverse association with stomach cancer and positive association with pancreatic cancer in men. Still other tumor sites showed "suggestive" associations with each of these exposure variables. In this study, age, race, sex, smoking, drinking, education, income, parity, foreign birth, marital status, and geographic location were used as stratification variables separately or in combination, to assess and control their potentially confounding effects and to examine interactions between exposure and control variables within a stratum. (41 refs.)

78-4715 **Tobacco Smoking, Occupation, and Malignant Tumors in the Rural Population of Vratsa, Bulgaria.** (Bul) Nikolov, I. (Oncology Res. Center, Medica Acad., Bulgaria); Stoianov, I.; Stoichev, I.; Draganov, I.; Pet kova-Bocharova, T.; Chernozemski, I. *Onkologiia* 14(2) 61-66; 1977.

Cancer incidence and its relationship to tobacco smoking an occupation were studied in 27 villages of the district of Vratsa, Bulgaria, during 1965-1974. Only subjects aged > 16 y were considered. Tumors were found in 315/46,913 smoker and in 239/61,244 nonsmokers. The relative risk of tumor of the mouth, stomach, urinary bladder, and, especially, o the bronchi and lungs was significantly higher among smokers than nonsmokers ($p < 0.001$), but there was no significant difference between these groups in the incidence cancer of the renal pelvis, ureter and urinary trac Compared with subjects of other occupations, far workers were found to have increased risk of skin canc (5.1x), cancer of the renal pelvis and ureter (3.3x bladder cancer (3.3x), gastric cancer (2.1x), and labi cancer (2.1x). (18 refs)

78-4716 **Energy Expenditure, Cigarette Smoking, an Blood Pressure Level as Related to Death fro Specific Diseases.** (Eng) Paffenbarger, R. S. (Dept. Famil Community and Preventive Medicine, Stanford Univ. Sc Medicine, Stanford, CA, 94305); Brand, R. J.; Sholtz, R. I Jung, D. L. *Am J Epidemiol* 108(1): 12-18; 1978.

In a 22-yr follow-up of 3,686 San Francisco longshoreme the roles of physical activity, cigarette smoking habit, an systolic blood pressure level were evaluated independently i relation to risk of death from a broad range of diseases. Smoking pattern and blood pressure status were established i 1951, and job activity was assessed annually during the fo low-up period. Heavy cigarette smoking predicted increase risk of death from heart attack (2.09), cancer (1.71; lung cancer, 3.19), chronic obstructive respiratory disease (2.63), an pneumonia (2.27). (12 refs.)

78-4717 **Mining, Lung Cancer and Smoking.** (Eng) Axelson, O. (Dept. Occupational Medicine, Regiona Hosp., Linkoping, Sweden); Sundell, L. *Scand J Work Environ Health* 4(1): 46-52; 1978.

Mortality from lung cancer during 1956-1976 was studied i smokers and nonsmokers who had worked in two adjacen Swedish zinc-lead mines. The local register of deaths an burials was used as a source of material, which included 2 cases of lung cancer and 174 controls who had died from causes other than lung cancer. (Controls were those 3 person who had died before and after each case.) There was a 16-fol increase in lung cancer mortality among the miners. Significantly more of the lung cancer cases (72%) had been expose to underground mining than the controls (11%). Althoug the risk of dying from lung cancer was higher for nonsmoker han for smokers, smoking miners had a higher risk of deveoping lung cancer than would be expected from smoking lone. Furthermore, the av induction-latency time for lung ancer was about 9 yr shorter for the smokers than for the onsmokers, and the smokers died from lung cancer approxinately 11 yr earlier than the nonsmokers. It is possible that moking increases the thickness of the bronchial mucus layer, hereby protecting the bronchial epithelium from alpha radiaion due to Radon daughters. However, after the radiogenic nduction of carcinogenesis, tobacco smoke might have a pronoting effect. (20 refs)

78-4718 **Incidence of Salivary Gland Neoplasms in Greenland with Special Reference to an Anaplastic Carcinoma.** (Eng) Nielsen, N. H. (Univ. Inst. Forensic Medicine, Frederik V's vej 11, DK-2100 Copenhagen 0, Denmark); Mikkelsen, F.; Hansen, J. P. *Acta Pathol Microbiol Scand (A)* 86(2): 185-193; 1978.

The incidence and histopathology of 42 salivary gland neoplasms (17 benign, 25 malignant) diagnosed between 1955 and 1974 in Greenland are reviewed. The 25 malignant tumors occurred in 10 men and 15 women 12-68 yr of age. The yearly incidence rates between 1965 and 1974, age-adjusted to the European standard population, were 4.5/100,000 for men and 9.6/100,000 for women; the observed/expected ratios during this period were 7.5 for men and 9.2 for women. Twenty-two malignant tumors were located in the parotid gland, 2 were in the submandibular gland, and 1 was in the palate. Histological classification indicated 1 mucoepidermoid tumor, 1 adenoid cystic carcinoma, and 23 undifferentiated, anaplastic carcinomas histologically identical to malignant lymphoepithelial lesions. The 5-yr determinate survival rate was only 14%. It is suggested that virus infection and/or dietary deficiencies may be etiological factors in these tumors; however, secondary nasopharyngeal carcinoma could not always be excluded. (50 refs.)

78-4719 **Environmental Factors in the Pathogenesis of Thyroid Cancer.** (Ita) Gubetta, L. (Instituto di Anatomia Patologica, Centro Studi sulla Endemia di Gozzo, Ospedale Mauriziano, Torino, Italy); Costa, A. *Minerva Med* 69(34): 2313-2320; 1978.

Between 1957 and 1974, 227 cases of thyroid cancer were diagnosed at a Northern Italian hospital. The increasing incidence of this neoplasm in the area served by the hospital is connected with a geographical factor. The disease has been shown to be most prevalent in two mountainous areas of endemic goiter (1.46 and 2.16 cases/100,000 inhabitants, respectively, as opposed to an av national incidence of 0.74/100,000). High levels of thyrotropin have also been linked to thyroid cancer. Animal experiments on the effects of iodine-deficient diets, thyrotropin administration and partial thyroidectomy are cited. Histologically, papillary carcinomas, the most common type of thyroid cancer, were less common than follicular carcinomas; however, since 1969, the number of papillary lesions increased, possibly due to population changes (immigration from the South, migration to the cities). Undifferentiated forms of tumor increased least. Ionizing radiation may also contribute to the development of thyroid cancer: of 15 young people in the hospital series, 7 had received therapeutic irradiation 10-12 yr prior to tumor appearance. (61 refs.)

78-4720 **Development of Thyroid Carcinoma in Residents of a Region Endemic for Goiter.** (Rus) Neimark, I. I. (Dept. Surgery, Second Railroad Clinical Hosp., Barnaul, USSR); Timoshnikov, V. M. *Probl Endokrinol (Mosk)* 24(3): 28-32; 1978.

An attempt was made to evaluate the role of various factors in the etiology of thyroid cancer. Of 338 patients with malignant thyroid tumors, 106 were residents of a region of the Altai Mountains, USSR, that is endemic for goiter. Ninety-nine patients had eu- and hypothyroidism; only 7 had symptoms of hyperthyroidism. A history of endemic goiter was found in 86.6% of the patients. The cancer patients had significantly decreased levels of iodine in the thyroid tissue (1.9725 g% compared with 3.9676 g% in healthy subjects and 2.2897 g% in patients with goiter only), and increased levels of copper (27.011 mg%, compared with 14.97 mg% in healthy subjects and 18.54 mg% in patients with goiter) and cobalt (6.204 mg%, compared with 2.65 and 4.42 mg%, respectively). (14 refs.)

78-4721 **Thyroid Carcinoma in Kenya.** (Eng) McGill, P. E. (Westwood Hosp., Beverley, N. Humberside, England). *Trop Geogr Med* 30(1): 82-86; 1978.

Thyroid carcinoma was diagnosed between 1964 and 1969 in 63 Kenyans of African origin. Most of the tumors were histologically differentiated; the female:male ratio was approx 5:1. Follicular tumors were found mainly in highland tribes in which endemic goiter is known or presumed to exist; papillary carcinoma predominated in lowland tribes. (25 refs.)

78-4722 **Dose Assessment Analogies.** (Eng) Lindell, B. (Swedish Natl. Inst. Radiation Protection, Fack, S-104 01 Stockholm, Sweden). *Environ Health Perspect* 22: 75-78; 1978.

Assessments of radiation risks are based on the absorbed dose in the organs and tissues of interest, and they assume a linear, nonthreshold dose-response relationship for cancer induction or genetic effects at low doses. Similar assessments may be made for nonradioactive, mutagenic or carcinogenic substances. The quantity that would correspond to the absorbed radiation dose as the basis for risk assessment would be time integral of the local tissue concentration of the carcinogen, which may not be identical for inhaled or ingested substances. The assessment involves calculations that are very similar to those made in the assessment of radiation risks. Such estimates for nonradioactive pollutants would provide a more appropriate basis for comparisons with radiation risks. In the cases of lung cancer, the risk is assumed to be proportional to the total amount of carcinogen inhaled. (5 refs)

78-4723 **Offspring of Childhood-Cancer Survivors (Meeting Abstract).** (Eng) Li, F. P. (NCI, Bethesda, MD, 20014); Holmes, F. F.; Holmes, G. E.; Jaffe, N. *Proc Am Assoc Cancer Res* 19: 218; 1978. (no refs)

78-4724 **Studies of the Mortality of A-Bomb Survivors. 6. Mortality and Radiation Dose, 1950-1974.** (Eng) Beebe, G. W. (Clinical Epidemiology Branch, NCI, Bethesda, MD, 20014); Kato, H.; Land, C. E. *Radiat Res* 75(1): 138-201; 1978.

This updated (through 1974) study of cancer deaths among atomic bomb survivors provides more evidence of the carcinogenic effect of radiation. The relative and absolute risk estimates for 1971-1974 (1.48 and 4.19) were similar to those for 1967-1970 (1.28 and 3.32); the overall estimates for 1950-1974 were 1.29 and 2.21, respectively. In addition to leukemia and thyroid, breast, and lung cancer, cancer of the esophagus, stomach, and urinary organs and the lymphomas should be included among the cancers caused by the ionizing radiation from the explosions. Evidence of radiation carcinogenesis is much stronger for Hiroshima than for Nagasaki victims of the bombs. The leukemogenic effect was still present during 1970-1974, having lasted longer than anticipated, but it is declining. The av absolute risk for other malignant neoplasms now exceeds that for leukemia. Accumulating evidence of radiation-induced cancer in an increasing number of tissues shows that most tissues may have been sensitive to the radiation delivered by the bombs. The minimal latent period for most of the carcinogenic effects was <15 yr and it depended on age and cancer site. Age in 1945 played an important but variable role in the carcinogenic effect, but one that cannot be understood fully without further study. This study rejects the hypothesis that radiation accelerates natural aging, and it concludes that the results of exposure to large, single doses of ionizing radiation are focal and largely confined to cancer. (36 refs)

78-4725 **Army Technologists: 29-Year Follow up for Cause of Death.** (Eng) Jablon, S. (Medical Follow-up Agency, Natl. Acad. Sciences-Natl. Res. Council, Washington, DC); Miller, R. W. *Radiology* 126(3): 677-679; 1978.

A previous 18-yr (1946-1963) follow-up study revealed no significant excess of cancer among men who served in the Army during World War II as radiological technologists (6,560), compared with men who served as medical, laboratory, or pharmacy technologists (6,826). Extension of the follow-up by 11 yr (1946-1974) revealed that 145 former radiological technologists had died of cancer compared to 158 controls. There were no statistically significant differences between these groups for individual sites of cancer or for deaths from other causes. There is, therefore, no evidence that military radiological technologists have suffered adverse effects as a consequence of their occupational exposures. (10 refs)

78-4726 **The Queensland Melanoma Project.** (Eng) Beardmore, G. L. (Queensland Melanoma Project, Princess Alexandra Hosp., Ipswich Road, Woolloongabba, 4102, Queensland, Australia). *Int J Dermatol* 16(10): 831-835; 1977.

Epidemiological data on 1,500 patients treated for malignant melanoma in Queensland, Australia, between 1963 and 1969 are presented. The yearly incidence was 16/100,000, with a sex distribution of 55% women and 45% men. No patient was $<$ 10 yr old; the smallest number of patients was in the 10- to 19-yr age group, the largest in the 40- to 49-yr age group. About 23% of the melanomas were $<$ 1.0 cm in diameter, 50% were 1.0-1.9 cm, 17% were 2.0-2.9 cm, and the remaining 10% were $\geq$3.0 cm. In men, 44% of the lesions were on the back; in women, 36% were on the lower limbs. Multiple primary cutaneous melanomas were observed in 4.8% of the patients. The 5-yr survival rate for the 1,500 patients was about 74%, with women having a better chance of survival than men (82% vs 65%). (8 refs.)

78-4727 **Skin Tumours in White South Africans. Part I. Patients, Methods and Incidence.** (Eng) Whiting, D. A. (Dermatology Section, Dept. Internal Medicine, Southwestern Medical Sch., Univ. Texas Health Science Center, 5323 Harry Hines Blvd., Dallas, TX, 75235). *S Afr Med J* 53(3): 98-102; 1978.

The incidence of skin tumors seen in whites recorded in a dermatological practice in the southern Transvaal region of South Africa between 1968 and 1975 is reported. A total of 4,861 skin tumors were diagnosed in 3,597/15,153 patients seen during this period. Solar keratosis (1,523 cases), seborrheic keratosis (624), basal cell carcinoma (574), intradermal nevus (428), polyps and skin tags (312), epidermal cysts (257), and keratoacanthomas (139) made up the majority of the lesions. Only 18 cases of malignant melanoma (versus an expected number of 30) were noted; this could be due to a low referral rate. (27 refs)

78-4728 **Various Epithelial and Non-Epithelial Tumors Spontaneously Occurring in Long-Lived Mice of A/St, CBA, C57BL/6 and Their Hybrid Mice.** (Eng) Kawada, K. (Dept. Pathology, Gifu Univ. Sch. Medicine, Tsukasa-machi 40, Gifu 500, Japan); Ojima, A. *Acta Pathol Jpn* 28(1): 25-39; 1978.

The incidence and pathological nature of various kinds of epithelial and nonepithelial tumors and tumorlike lesions that develop spontaneously in aged mice of strains A/St, C57BL/6, and CBA and of (C57BL/6 x CBA)F_1 hybrids were investigated. Mice were sacrificed at ages 13 to > 36 mo old. Tumor incidence was high in the CBA strain (55%) and in the hybrids (46.7%). In the A/St strain, epithelial tumors exceeded lymphoreticular neoplasms. Most of the neoplasms found in the C57BL/6 strain were lymphoreticular, and they occurred in the youngest age group in contrast to the other strains or the hybrids. Some tumors were successfully transplanted into the same strain of mice. A tumor line showing phagocytic activity and growing only in the liver, even when injected sc, was obtained from a reticulum cell neoplasm (Dunn type A) that had originated in the liver of a (C57BL/6 x CBA)F_1 hybrid male mouse. Additional tumors that were identified in this population included liver cell, mammary, pulmonary, renal, small intestinal, and islet cell carcinomas, ovarian and oviduct tumors, a cavernous hemangioma, angiosarcomas, and pheochromocytomas. (18 refs)

78-4729 **Incidence of Cancer in Relatives of Children with Retinoblastoma.** (Eng) Fedrick, J. (Unit Clinical Epidemiology, Univ. Oxford, Oxford, OX3 7LF, England); Baldwin, J. A. *Br Med J* 1(6105): 83-84; 1978.

The families of 11 patients with retinoblastoma (1 with bilateral disease) were interviewed to determine the incidence of cancer among the members. Five cancers were found compared to the 1.5 expected. Other family members reportedly had developed cancer, but the diagnosis could not be verified. (5 refs)

78-4730 **Relative Importance of Risk Factors in Bladder Carcinogenesis.** (Eng) Miller, C. T. (Health Protection Branch, Health and Welfare Canada, Ottawa, Canada); Neutel, C. I.; Nair, R. C.; Marrett, L. D.; Last, J. M.; Collins, W. E. *J Chronic Dis* 31(1): 51-56; 1978.

Responses from outpatients with urological complaints were recorded in a detailed questionnaire exploring potential risk factors in bladder cancer. The subjects were subsequently classified on the basis of hospital records as cancer cases or controls. Each of the 265 cases was matched to 2 controls of the same age and sex. History and treatment of tuberculosis of all subjects were verified through the four geographically adjacent tuberculosis registers. Analysis of exposures of matched triples revealed six statistically significant associations with bladder cancer in men [smoking, gout, allergies (self), allergies (family), occupational radiation exposure, and occupational exposure to chemicals.] In women, there was one significant positive association (coffee consumption) and one significant negative association (allergies, self). Although the relative risk of isonicotinic acid hydrazide (INH) exposure in women was the highest observed (3.0), the number of exposed individuals was too small to permit any meaningful conclusion. Discriminant analysis was used to rank the variables in order of their importance as potential risk factors. Statistically significant ability to discriminate cases from controls was observed in men for (1) allergy (family), (2) occupational exposure to radiation, (3) occupational exposure to chemicals, and (4) smoking. In women, the significant discriminators were (1) coffee consumption, (2) history of tuberculosis and INH treatment, and (3) allergy (self, protective effect). The suggestion that INH is a potential carcinogen indicates that further study of the association of the drug with bladder cancer is in order. (23 refs)

78-4731 **On the Endemic Occurrence of Papillomas. Evaluation of Environmental Factors in the Occurrence of Urothelial Tumors in the Province of Steiermark.** (Ger) Scholl, H. (Urologische Abteilung, Landeskrankenhaus, Auenbruggerplatz 1, A-8036 Graz, Austria); Narath, P. *Acta Chir Austriaca* 9(4): 99-103; 1977.

The features of benign bladder papillomas were evaluated in 888 patients (185 women, 703 men) from the province of Steiermark, Austria, and the effects of environmental pollutants (such as contamination of water with nitrosamines, bacteria, and minerals) on the incidence of these tumors were determined. There was a 2.5-fold higher morbidity in industrial regions than in agricultural areas. These higher morbidity areas also had increased sulfur dioxide and dust levels in the atmosphere. There were no indications that bladder papillomas were endemic to the Steiermark region. Industrial air pollution had a greater influence on the incidence of papillomas than groundwater pollution. The highest morbidity rate was observed around Graz, and it was attributed to an increase in air pollution as a result of automobile exhausts and poor air circulation. Because of the threefold increase in the incidence of bladder papillomas in areas with excessive pollution, it is suggested that the benign nature of the papillomas be reevaluated. (10 refs.)

78-4732 **Epstein-Barr Virus Infections in Brazil. II. Hodgkin's Disease.** (Eng) Evans, A. S. (Dept.

Epidemiology and Public Health, Sch. Medicine, Yale Univ., 60 College St., New Haven, CT, 06510); Carvalho, R. P.; Frost, P.; Jamra, M.; Pozzi, D. H. *J Natl Cancer Inst* 61(1): 19-26; 1978.

Antibody levels to Epstein-Barr virus (EBV) and to eight other viral antigens were tested in 67 Brazilian patients with Hodgkin's disease (HD) and matched healthy controls. Antibody to the viral capsid antigen (VCA) of EBV was tested with the use of the Jijoye line as a source of antigen. Antibody was present in the sera (diluted 1:10) of all 67 HD patients, and it was elevated to 1:320 or greater in 31.3%; the geometric mean titer (GMT) was 1:146. In 46 patients tested with the use of the EB-3 cell line as a source of antigen, all sera again showed the presence of antibody; 28% had elevated titers of 1:320 or greater, and the GMT was 1:110. Titers were highest in men, in patients aged 30-39 yr, in severe forms of HD, and in Stage 2 disease, although none of these differences was statistically significant. There was a statistically higher GMT and a higher frequency of elevated titers in the patients than in the controls. Heterophile antibody and EBV-specific IgM antibody levels were not elevated in HD patients with respect to controls, but 20.5% of the HD patients had antibody to the early antigen of EBV in their sera. Antibody levels for herpes simplex virus, cytomegalovirus, rubella, measles, papovavirus, and parainfluenza viruses in HD patients were not significantly elevated over those of the controls. It appears that enough epidemiologic and virologic evidence points to a relationship between EBV and some cases of HD to merit further evaluation of the role of EBV in the pathogenesis of HD. (39 refs)

78-4733 **Geographical Distribution of Respiratory Tract Tumors in Upper Silesia.** (Pol) Zemla, B. (Instytut Onkologii, ul. Wybrzeze Armi Czerwonej 15, 44-101 Gliwice, Poland). *Nowotwory* 27(3): 249-254; 1977.

The results of an epidemiological survey of the incidence of malignant respiratory tract tumors among the urban population of Upper Silesia, Poland, are presented. Tumor incidence per 100,000 individuals in different localities ranged from 9.3 to 24.2, and the tumors were more frequent among men than women (ratio 4.64:1). There was a higher incidence in men above age 45 and in women over age 64. (no refs.)

78-4734 **The Epidemiology of Primary Liver Cancer Based on Tests of Autopsy Material over the Period 1962-1975.** (Pol) Zielinska, K. (Inst. Pathomorphological Diagnostics, Medical Center Postgraduate Education, Warsaw-Bielany Hosp., Warsaw, Poland); Czorniuk, A.; Kobuszewska-Faryna, M. *Pol Tyg Lek* 32(43): 1669-1672; 1977.

A review of autopsy material at a Warsaw hospital revealed 61 cases of primary liver cancer (1.2% of all autopsies performed over a 13-yr period). The cancer cases included 49 men and 12 women. Cirrhosis (excluding biliary and cardiac cirrhosis) was present in 58 of the cases, and it was four times more frequent in men than in women. The patients lived in a district in which the av mortality rate from liver cancer in the period 1970-1975 was 6.03 for men and 1.68 for women. (18 refs.)

78-4735 **Hepatocellular Carcinoma and Hepatic Cirrhosis in the West of Scotland: A 25-Year Necropsy Review.** (Eng) Burnett, R. A. (Dept. Pathology, Univ. Glasgow, Glasgow G11 6NT, Scotland); Patrick, R. S.; Spilg, W. G.; Buchanan, W. M.; MacSween, R. N. *J Clin Pathol* 31(2): 108-110; 1978.

The incidence of hepatocellular carcinoma and hepatic cirrhosis in five hospitals in Western Scotland between 1950 and 1974 was studied retrospectively, based on a necropsy review of 313 cases. During this period, the necropsy incidence of the tumor rose to twice its original level, and this trend was noted for both men and women. However, the tumor was found four times more often in men than in women. A comparison of the cirrhosis and tumor incidence in three hospitals indicated that the incidence of cirrhosis remained stable until the last half-decade, when it increased. It is suggested that cirrhosis acts as a promoting agent in the presence of a primary carcinogenic agent(s); this does not exclude the possibility that the same agent(s) may express both a cirrhogenous and/or carcinogenic effect in some persons. (9 refs)

78-4736 **The Changing Pattern of Liver Disease in South African Blacks.** (Eng) Isaacson, C. (Dept. Pathology, Sch. Pathology, South African Inst. Medical Res., Johannesburg, S. Africa). *S Afr Med J* 53(10): 365-368; 1978.

The pattern of liver disease in South African Blacks was studied by reviewing the results of 201 liver biopsies performed between 1959 and 1960 and 729 biopsies performed between 1975 and 1976. Changes were noted in the histological appearances of micronodular cirrhosis. During the latter period, there were more instances of fatty change, alcoholic hepatitis, alcoholic hyalin, and alcoholic cirrhosis. These changes are presumably related to the liberalization of the liquor laws in 1962. Prior to that time, alcohol consumption by blacks was confined to home-brewed beverages containing large quantities of iron derived from the containers in which the liquor was brewed. No change in the histological pattern or incidence of macronodular cirrhosis and hepatocellular carcinoma was observed. A total of 22 cases of hepatocellular carcinoma were diagnosed during the first period, 77 during the second. Twenty-one cases showed an associated macronodular cirrhosis, 10 an associated micronodular cirrhosis. (13 refs)

78-4737 **Occupational Cancers of the Ethmoid Region.** (Fre) Haguenauer, J. P. (Societe de medecine du travail et d'ergonomie de Lyon, 8, avenue Rockefeller, 69373 Lyon Cedex 2, France); Romanet, P.; Duclos, J. C.; Guinchard, R. *Arch Mal Prof* 38(9): 819-823; 1977.

In a series of 115 patients with cancer of the ethmoid region, 32 worked in a variety of occupations related to wood. Thirty of these patients had an adenocarcinoma and 2 had either an adenocarcinoma or a reticulosarcoma. The usual duration of exposure was 14-15 yr. At the time of diagnosis, 27 were still working, 2 had retired (2 and 12 yr, respectively), and 3 had been in other occupations for 11, 15, and 30 yr, respectively. An additional patient in the series was a woman with adenocarcinoma who was the wife of a cabinet maker; she had lived above the shop for 10 yr. The etiological agent responsible for the cancers is thought to be tannin, because: (1) workers involved with high-tannin-content wood such as oak and chestnut are more likely to develop cancer of the ethmoid and (2) workers in tanneries and leather factories also have a high incidence of ethmoid cancer. Other agents thought to be responsible for cancers of the ethmoid region or nasal fossae are nickel, radium, asbestos, and hexamethylphosphoramide. (no refs.)

78-4738 **Usefulness of Population Controls in Retrospective Studies of Alcohol Consumption. Experience from a Case-Control Study of Esophageal Cancer in Ille-et-Vilaine, France.** (Eng) Jensen, O. M. (Unit Epidemiology and Biostatistics, International Agency Res. Cancer, 150 cours Albert Thomas, 69008 Lyon, France); Tuyns, A. J.; Pequignot, G. *J Stud Alcohol* 39(1): 175-182; 1978.

In a study of the association of alcohol consumption with esophageal cancer, controls were taken from patients hospitalized for non-alcohol-related diseases and from the general population, and the effectiveness of the two groups as controls was compared. Both control groups had similar rates of alcohol consumption. (23 refs)

78-4739 **General and Etioepidemiological Characteristics of Cancer of the Upper Respiratory and Digestive Tracts.** (Fre) Cachin, Y. (Departement de chirurgie cervico-faciale et ORL, Institut Gustave-Roussy, 16 bis, avenue Paul-Vaillant-Couturier, 94800 Villejuif, France). *Rev Prat* 28(31): 2359-2364; 1978.

According to statistics compiled in 1967, cancers of the upper respiratory and digestive tracts (URD) represent 12% of all cancers and 8% of cancer deaths in France. The epidemiology of URD cancers is discussed on the basis of 5,748 patients observed at the Gustave-Roussy Institute from 1959 to 1970. Approx 95%-97% of these patients were men. A high proportion of patients with cancers of the tongue, oropharynx, hypopharynx, and esophagus were alcoholics. Alcoholics did not have a high incidence of cancers of the nasal cavity and sinuses or the rhinopharynx. Cancers at these sites were more likely to occur among persons in certain occupations, such as woodworkers, carpenters, asbestos miners, and nickel workers. Heavy smokers tended to develop cancers of the same areas as alcoholics in addition to cancers of the lung, lip, and buccal cavity. Again, tobacco usage was not strongly associated with cancers of the upper respiratory tract, such as the nasal cavities and rhinopharynx. URD cancers have a varied incidence in relationship to geographical region and sex. Examples of these variations are provided. (no refs)

78-4740 **Oesophageal Carcinoma in India. Some Epidemiologic and Morphologic Considerations.** (Eng) Mehrotra, M. L. (Dept. Pathology, Inst. Medical Science, Banaras Hindu Univ., Varanasi, India); Lal, H.; Pant, G. C.; Vaidya, M. P.; Gupta, I. M. *Trop Geogr Med* 29(4): 353-358; 1977.

The frequency of esophageal carcinoma in relation to gastrointestinal tract and total malignancies was investigated in a hospital population in Varanasi, India. The 202 patients who presented with this carcinoma comprised 2.39% of all malignancies and 17.11% of all gastrointestinal tract malignancies noted between 1964 and 1975. The highest tumor incidence occurred in the sixth decade of life with a male: female ratio of 2.2:1. This ratio decreased with age from 3:1 in the fourth decade of life to 1.7:1 in the seventh. The tumor involved the middle third of the esophagus in 104 patients, the lower third in 72, and the upper third in 26. Squamous cell carcinoma was the most frequent histologic type (193 cases), with 3 cases of adenocarcinoma and 6 of anaplastic carcinoma also being reported. The gross appearance of the lesion was fungating in 188 patients, fibromatous in 8, and crateriform in 6. (30 refs)

78-4741 **Epidemiology of Primary Cancer of the Bronchus in the African Negro.** (Fre) Schmidt, D. (Service de Pneumophtisiologie, CHU de Treichville, BPV 13, Abidjan, RCI, Ivory Coast, W. Africa); Sanchez, J.; Tiendrebeogo, H.; Roudaut, M. *Nouv Presse Med* 7(21): 1827-1830; 1978.

Epidemiological data are presented on 86 Ivory Coast African negroes (81 men, 5 women) with primary cancer of the lung observed over a 5-yr period (1972-1976). The av age of the patients was 50.4 yr, and 68% were >45 yr of age. Risk appeared higher in the rural population, as 56% of the patients were from rural areas. Tobacco use was definitely related to the development of cancer: 70/86 patients were smokers. Precise data on tobacco use were obtained in 63 patients: 51 smoked for >20 yr and 44 smoked >20 cigarettes per day. The Ivory Coast is free of industrial pollution; however, brush fires are frequent and the wood carbon is redistributed by the prevailing winds. Tuberculosis is endemic in the Ivory Coast (3,000 new cases/yr in a population of 4 million), and tuberculosis preceded the lung cancer in 8/86 patients. (20 refs)

78-4742 **Development of Carcinomas in Billroth II-Resected Stomachs.** (Ger) Radomsky, J. (Chirurgische Klinik, Krankenhaus Nordwest, D-6000 Frankfurt am Main-Praunheim, W. Germany); Alken, P. *Therapiewoche* 28(8): 1609; 1978.

From 1964 to 1976, gastric resection was performed in 3,000 patients: for gastric ulcer in 1,807, for primary gastric tumors in 1,156, and for carcinoma of the gastric stump after Billroth II gastric resection in 37. The underlying disease that necessitated the Billroth II resection was gastric ulcer in most cases. The av latent period after the first surgery was 27.8 yr. The gastric stump carcinoma was localized to the anastomotic ring in 46% of all patients, it invaded the gastroenterostomy and the entire gastric stump in 35%, and it was distant from the anastomosis in 19%. These observations and literature data indicate that there is an increased risk of gastric stump carcinoma after Billroth II gastric resection. (no refs)

78-4743 **Epidemiology of Gastric Cancer. Part II.** (Ger) Wolff, G. (Regierungskrankenhaus, Scharnhorststrasse 37, DDR-104 Berlin, E. Germany); Lauter, J. *Arch Geschwulstforsch* 47(6): 531-540; 1977.

A comparison of 257 patients with gastric cancer and 766 patients with different stages of chronic gastritis or normal gastric mucosa revealed several common variables between the cancer and gastritis groups. However, the former could be distinguished from the latter by exposure to carcinogens, social class, genetic factors, and digestive diseases. It is suggested that these factors are important to the etiology of gastric cancer in atrophic gastritis patients. (13 refs.)

78-4744 **Cancer Incidence in the Province of Zaragoza from 1970 to 1974.** (Spa) Zubiri, A. (Junta Provincial, Asociacion Espanola Contra el Cancer, Joaquin Orus, Zaragoza 1, Spain). *Rev Esp Oncol* 24(2): 323-348; 1977.

The incidence of cancer was studied in the province of Zaragoza, Spain, during 1970-1974. The incidence per 100, 000 was found to rise progressively from 176.9 during the 1960-1964 to 195 during 1965-1969 and to 237.8 during 1970-1974. The mean annual incidence during 1970-1974 was 259.8 for men and 216.6 for women. The mean annual incidences were 9.58 (17.07 in men and 2.38 in women) for tumors of the buccal cavity and pharynx; 77.39 (84.61 in men and 70.44 in women) for tumors of the digestive and peritoneal organs; 29.67 (51.92 in men and 8.28 in women) for tumors of the respiratory tract; 45.28 (26.33 in men and 63.5 in women) for tumors of the bones, soft tissues, skin, and breast; 42.22 (48.63 in men and 36.05 in women) for tumors of the genitourinary organs; and 30.97 (27.46 in men and 34.34 in women) for tumors of other localizations. Tumors of the stomach were most frequent in men (43.41 in 1965-1969 and 43.73 in 1970-1974), followed by malignant neoplasms of the lungs, bronchus, and trachea (24.68 in 1965-1969 and 34.36 in 1970-1974). Among women, breast cancer was most frequent (46.41), followed by stomach cancer (29.93) during 1970-1974. The incidence of urinary bladder cancer increased considerably in men from 6.68 during 1965-1969 to 15.83 during 1970-1974. (6 refs)

78-4745 **Characteristic Features of Morbidity due to Rectal Carcinoma.** (Rus) Bul'bulian, M. A. (Cancer Res. Center, Moscow, USSR); Knysh, V. I. *Vestn Akad Nauk SSSR* (5): 86-90; 1978.

The incidence, distribution, and etiology of rectal carcinoma are discussed briefly, and the morbidity and mortality indices for this neoplasm in the Soviet Union are presented. The standardized mortality index increased from 2.2 in 1960 to 4.3 in 1972. The highest incidence of rectal carcinoma was observed in individuals > 70 yr-old, and it was 210 and 146 times greater than the respective incidences in men and women < 30-yr-old. (30 refs)

78-4746 **Environment and Cancer.** (Eng) Sahyun, M. R. (St. Paul, MN). *Chem Eng News* 56(12): 43-44; 1978.

The death rate from cancer in the US population for 1974 was estimated using the years 1900-1960 as a baseline for computation. The observed death rate was 13% higher than that expected. This 13% represents fatal neoplasia having a new and presumably environmental etiology. Extrapolation of present trends to the year 1995 indicated a death rate 21% higher than that tabulated from the historical baseline; ie, the excess morbidity due to new etiological factors is 21% of the total. Thus, this 13%-21% range in upper limit values is more representative of actual environmental hazard. (no refs)

78-4747 **Cancer Morbidity in 1975.** (Eng) Rahim, M. A. (Radiotherapy Unit, Medical Coll. Hosp., Dacca, Bangladesh); Choudury, M. H.; Sarma, S. K.; Ahmed, Q. A.; Hossian, M. A. *Bangladesh Cancer Rep* 1(1): 11-17; 1977.

The Bangladesh cancer incidence for 1975 is reported by site. The incidence of cancer of the larynx, lungs, and oropharynx was high in men, and the incidence of cancer of the cervix uteri, breast, and oral cavity was high in women. There was also a high incidence of male breast cancer, with the male:-female ratio being 1:10.8. (10 refs)

78-4748 **Lakes Area Tumor Service Registry: Report 1970-1975.** (Eng) Patterson, J. C. (Lakes Area Tumor Service Registry, Roswell Park Memorial Inst., 666 Elm St., Apartment 3G, Buffalo, NY, 14263). (Buffalo: Roswell Park Memorial Inst.): 85 pp.; 1975.

Survival and deomographic data are presented for 16,463 cases of malignant disease treated at 24 western New York and neighboring Pennsylvania hospitals between January 1970 and December 1975. The data, collected by the Lakes Area Tumor Service Registry, include cancer incidence by site, sex, age distribution, stage of disease at diagnosis, and treatment. (no refs)

78-4749 **Abnormal Cell Proliferation in Human Lithiasic Gallbladder Mucosa (Meeting Abstract).** (Eng) Putz, P. (Gastrointestinal Unit, Vrije Universiteit Brussels, Brussels, Belgium); Willems, G. *Digestion* 16(3): 269; 1977.

78-4750 **The Register on Effects for the Clean Air Program in the Cologne District.** (Ger) Zimmermeyer, G. (Essen, W. Germany). *Staub-Reinhalt Luft* 38(6): 222-226; 1978.

The legal and environmental bases for the second Clean Air Program for the Western Ruhr District are presented, together with the results of epidemiological studies and investigations on plants and various elements. The Clean Air Program contains information on the type and extent of observed and expected air pollutants and their environmental consequences, observations on the causes of air pollution, and recommendations for limiting the air pollution. The program's register on the effects of pollution on humans in the district contains information on carboxyhemoglobin, carcinoembryonic antigen, complement C-3, max lung capacity, blood lead concentrations, sputum immunoglobulin content, and the condition of tonsils and cervical and mandibular lymph nodes. In addition, observations were made on lung cancer, bronchitis, sinusitis, benzpyrene, and phenol. A register of effects on plant material covers the exposure of lichens, standardized grass samples, and various selected crops and feed material to the various air pollutants. There is no conclusive evidence that high air pollution levels in Duisburg have had a detrimental health effect on area residents. There is, however, evidence indicating that the disease incidence in clean air districts is similar to that in the polluted Duisburg area. (2 refs.)

78-4751 **The Benefits of Catastrophe: A Major Reduction in Tumor Prevalence Associated with Greatly Diminished Frog Populations (Meeting Abstract).** (Eng) McKinnell, R. G. (Univ. Minnesota, Saint Paul, MN, 55108); Gorham, E.; Martin, F. B.; Schaad, J. W. *Proc Am Assoc Cancer Res* 19: 212; 1978. (no refs)

78-4752 **Clinical Investigations of the Etiology of Childhood Cancers (Meeting Abstract).** (Eng) Jaffe, N. (Sidney Farber Cancer Inst., Boston, MA, 02115); Marchetto, D. J.; Meadows, A.; Winston, K. R.; Li, F.P.; Scher, C. D. *Proc Am Assoc Cancer Res* 19: 157; 1978. (no refs)

78-4753 **Quantitative Theories of Carcinogenesis.** (Eng) Whittemore, A. (Hunter Coll., City Univ. New York, New York, NY); Keller, J. B. *SIAM Rev* 20(1): 1-30; 1978.

Several mathematical theories of carcinogenesis are presented. These theories involve the transformation of a normal cell and the subsequent proliferation of the transformed cell and its descendants to form a tumor. They predict the rate of tumor occurrence as a function of time and of the concentrations of the agents that cause transformation or accelerate growth. The consequences of these theories are compared with data on human cancer incidence and with laboratory findings. A new theory is presented that includes features of previous theories but that also describes the results of initiation-promotion experiments. The present theories do not distinguish between benign and malignant tumors and they do not include the possibility of cell repair and the action of the immune system. (36 refs.)

78-4754 **Skin Tumours in White South Africans. Part IV. Influence of Occupation, Sun Sensitivity, Colouring and Associated Skin Tumours on the Incidence of Skin Tumours.** (Eng) Whiting, D. A. (Dermatology Section, Dept. Internal Medicine, Southwestern Medical Sch., Univ. Texas Health Science Center, 5323 Harry Hines Boulevard, Dallas, TX, 75235). *S Afr Med J* 53(5): 162-166; 1978.

The effect of occupation, sun sensitivity, coloring, and associated skin tumors on the incidence of skin tumors in white South Africans in the southern Transvaal was investigated. Outdoor and industrial occupations did not increase the incidence of any skin tumor except that of squamous cell carcinoma. However, they did accelerate the onset of solar keratoses and squamous and basal cell carcinomas. Fair and sun-sensitive skin, red hair, and blue eyes predisposed a person to the development of skin cancer. Significant associations included a large number of seborrheic keratoses with polyps, intradermal nevi with cavernous hemangiomas, and intradermal nevi with lentigines. A high proportion of solar keratoses was connected with squamous cell carcinoma, basal cell carcinomas with superficial basal cell carcinoma, and solar keratoses with Bowen's disease. Although 61% of the squamous cell carcinomas were associated with solar keratoses, only 2.5% of the patients with the latter had the former. Likewise, 64% of the patients with Bowen's disease had associated solar keratoses, but only 1% of the patients with the latter had the former. Only 1.6% of the patients with basal cell carcinomas had associated superficial basal cell carcinomas, and only 1/33 patients with Bowen's disease had an associated internal malignancy. (7 refs)

78-4755 **Density-dependent Limitation of Growth and the Regulation of Cell Replication by Changes in the Triggering Level of the Cell Cycle Switch.** (Eng) Gilbert, D. A. (Natl. Inst. Virology, P.O. Bag X4, Sandringham 2131, Transvaal, South Africa). *Biosystems* 9(4): 215-228; 1977.

The effects of altering the sensitivity threshold of a cell to initiation and suppression of proliferation were studied mathematically. Assuming the uptake of regulators by an equilibrium process, the various types of dependency of the max cell density on the initial level of the regulator (eg, serum) in the medium can be explained. Moreover, it may also be possible to distinguish whether an altered threshold or equilibrium constant is responsible for modified proliferation characteristics. The model suggests that some cells are more susceptible to control via changes in the relevant equilibrium constant and that others respond more markedly to threshold modulation. If control occurs through inhibition of replication, it is possible for the system to exhibit a critical mass; if this is exceeded, proliferation could continue indefinitely, provided adequate nutrients are available. An oscillator concept of the cell cycle accounts for the existence of a threshold, and it also permits a general understanding of its modulation by multiple agents. In cancer, a change in the regulator would only give rise to hyperplasia, a process that would continue until some factors became limiting. Competition between normal and cancer cells for the regulator would depend on the relative equilibrium constants: tumor cells would proliferate if the regulator is an inhibitor, but they would cease to replicate if it is a mitogen. Thus, tumors that fail to grow indefinitely would arise in tissue where control is exerted through mitogenic action. (28 refs.)

78-4756 **The Multistage Theory of Carcinogenesis and the Age Distribution of Cancer in Man.** (Eng) Moolgavkar, S. H. (Fox Chase Cancer Center, 7701 Burholme Ave., Philadelphia, PA, 19111). *J Natl Cancer Inst* 61(1): 49-52; 1978.

The multistage theory of carcinogenesis is discussed in relation to the age distribution of cancer in man. The incidence function predicted by the multistage theory of carcinogenesis can be expressed as an infinite (power) series that explicitly exhibits its dependence on transition rates and of which the Armitage-Doll approximation is the first nonzero term. When the transition rates are not small enough (about 10^{-4}/cell/yr), the second nonzero term in the series expansion makes an important contribution to the incidence function. In this case, the Armitage-Doll approximation is a poor one. This is illustrated by a hypothetical example that makes it possible to accomodate, within the multistage theory, the finding that many tumors show deviations below the incidence curve predicted by the Armitage-Doll approximation. Assumptions implicit in the theory have been ignored by some epidemiologists during their attempts to model age-specific incidence curves, and probabilities derived from population data have been confused with probabilities predicted by the model. The multistage theory as originally proposed is time-homogeneous, and no provision is made for a change in transition rates with changes in the environment. Hence, the theory can legitimately be applied only to cohort data for cancers that are not sensitive to environmental changes. (7 refs)

78-4757 **Diseases of Aging Untreated Virgin Female RFM and BALB/c Mice.** (Eng) Cosgrove, G. E. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Satterfield, L. C.; Bowles, N. D.; Klima, W. C. *J Gerontol* 33(2): 178-183; 1978.

Autopsies were performed on 278 RFM/Un and 331 BALB/c germfree-derived, specific-pathogen-free mice used as controls in a radiation experiment, and the incidence of various diseases was calculated. The incidence of neoplastic disease was 88% in the RF mice, 94% in the BALB/c mice. A total of 78% of the RF and 67% of the BALB/c mice developed leukemia or lymphoma. Most of these (67% and 61%, respectively) were reticulum cell sarcomas. However, RF mice had an 8% incidence of thymic lymphoma, compared with 1% in BALB/c mice. Lung tumors were found in 26% of the RF mice and 32% of the BALB/c mice; the most significant difference between the strains occurred with adrenal cortex neoplasms (< 1% for RF and 29% for BALB/c mice). A total of 98% RF mice and 74% BALB/c mice had glomerulosclerosis; high incidences of uterine hyperplasia, adrenal cortical atrophy, and edema were also noted. BALB/c mice tended to live approx 100 days longer than RF mice. The findings for RF mice are compared to literature data from previous experiments with this strain. (20 refs)

78-4758 **Organ Culture of Canine Prostate.** (Eng) Herwig, K. R. (Section Urology, Depts. Surgery, Anatomy, Univ. Michigan Medical Center, Ann Arbor, MI, 48109); Fischer, T. V.; Burkel, W. E.; Kahn, R. H. *Invest Urol* 15(4): 291-294; 1978.

Studies were conducted to develop a reliable culture preparation of dog prostate explants. All explants were interpreted in a double-blind fashion using a specific list of observable variables with defined limits for each. A multiple channel counter tabulated the information on epithelial states, and the data were stored in a computer system for statistical analysis. Explants of canine prostate were minimally maintained when cultivated in Trowell's T-8 medium supplemented with testosterone and insulin. Pretreatment of the dog with methylprednisolone (30 mg/kg im 2 hr before prostate removal) or addition of vitamin A (25 or 50 IU) to the culture medium markedly improved the maintenance of normal structure. Methylprednisolone pretreatment and the addition of vitamin A had a significant effect. Extrapolating any clinical significance of the effect of a glucocorticoid and vitamin A on the intact prostate is still speculative, but the findings suggest that it may be possible to develop a steroid of clinical usefulness for modifying the differentiation of the prostate. 78-4761 **Vitality of Tumor Fragments as a Function of Temperature. Correlation with Electrical Impedance.** (Fre) Santini, R. (Laboratoire de Physiologie pharmacodynamie, I.N.S.A., Batiment 406, 20, avenue Albert-Einstein, 69621 Villeurbanne Cedex, France); Lenoir, J.; Jenin, P.; Thomasset, A. *C R Acad Sci [D] (Paris)* 285(15): 1363-1365; 1977.

The ability of fragments of a Walker 256 rat carcinoma to develop an sc tumor in another rat was determined following heat treatment. The tumorigenicity of the fragments disappeared after they were treated for 150 min at 37 C, 80 min at 41 C, and 10 min at 44 C. Study of the electrical impedance of the tumor fragments showed a good correlation between regeneration after heat treatment and impedance only at 37 C. (9 refs.)

78-4762 **Spontaneous Transformation of Bovine Lens Epithelial Cells. Kinetic Analysis and Differentiation in Monolayers and in Nude Mice.** (Eng) Courtois, Y. (Unite de recherches querontologiques, INSERM U 118, 29, rue Wilhem, F-75016 Paris, France); Simonneau, L.; Tassin, J.; Laurent, M. V.; Malaise, E. *Differentiation* 10(1): 23-30; 1978.

Bovine lens epithelial cells are known to perform two determined functions in vivo. They synthesize the lens capsule and, in the germinal region, they differentiate in fiber cells with massive production of crystallin proteins, inactivation, and pyknosis of the nucleus. Adult bovine lens epithelial cells can be cultured, but no massive crystallin production has been demonstrated in vitro. In long-term cultures, they spontaneously acquired many characteristics of transformation: unlimited growth potential, abnormal karyotype, and multilayering. Viral particles were detected rarely. However, the cells retained their epithelioid character and the ability to synthesize lens capsule material. The kinetic characteristics of the cells were determined. When injected into nude mice, the cells proliferated and formed tumors in which synthesis of α-crystallin was demonstrated. These results show that in vitro transformation of lens epithelial cells does not affect their potential for terminal differentiation. (30 refs)

78-4763 **Androgen-Dependent Human Prostatic Carcinoma Tumor Line in Nude Mice (Meeting Abstract).** (Eng) Reid, L. (Albert Einstein Sch. Medicine, Bronx, NY, 10461); Leav, I.; Merk, F.; Albert, J.; Geller, J. *Proc Am Assoc Cancer Res* 19: 151; 1978. (no refs)

78-4764 **Accumulation of Spermidine and Spermine in Ehrlich Ascites Tumor Cells During Plateau**

Phase Growth. A Function of an Increased Fraction of G2 Phase Cells and Polyploid Cells. (Eng) Andersson, G. (Dept. Zoophysiology, Univ. Lund, Helgonavagen 3, S-223 62 Lund, Sweden); Osterberg, S.; Heby, O. *Int J Biochem* 9(4): 263-267; 1978.

The effect of plateau-phase growth on the accumulation of the polyamines spermidine and spermine in Ehrlich ascites tumor cells was determined. Transplantation of 7-day-old Ehrlich ascites tumor cells into new hosts resulted in a rapid induction of polyamine synthesis. During the first 2 hr, the activities of L-ornithine decarboxylase (ODC; putrescine synthesis) and S-adenosyl-L-methionine decarboxylase (AMD; spermidine and spermine synthesis) increased approx 9.5 and 7 times, respectively. ODC activity rose to a peak value 8 hr after transplantation, but AMD activity dropped between 2 and 6 hr before showing a second peak at 10-12 hr. Subsequently, both enzyme activities decreased continuously with tumor growth, and they exhibited high positive correlations with the rate of cell proliferation. Despite the decrease in polyamine synthesis, there was an accumulation of spermidine and spermine during plateau-phase growth. Further studies showed that the increase in spermidine and spermine was due to an accumulation of cells in the G2 phase of the diploid cell cycle and in the G1 phase of the tetraploid cell cycle. (22 refs)

78-4765 **Hormone-responsive Growth In Vivo of a Tissue Culture Cell Line Established from the MT-W9A Rat Mammary Tumor.** (Eng) Sirbasku, D. A. (Dept. Biochemistry and Molecular Biology, Univ. Texas Medical Sch., Houston, TX, 77025). *Cancer Res* 38(4): 1154-1165; 1978.

The in vivo growth properties of the MTW9/PL cell line, established in culture from a parent MT-W9A hormone-responsive rat mammary tumor, are reported. The MTW9/PL cells are epithelial and grow in culture medium supplemented with a wide variety of sera. When these cells were injected into W/Fu rats, tumor formation was noted in normal females, estrogen-treated males, estrogen-treated ovariectomized females, and estrogen-treated castrated males. Only 0%-30% tumor formation occurred in ovariectomized females or castrated males, and the tumors that formed in gonadectomized hosts were usually smaller than those formed in normal or estrogen-treated hosts. Both progesterone and testosterone were capable of promoting tumor formation in ovariectomized females; hydrocortisone inhibited estrogen-promoted growth. Supraphysiological levels of estrogen inhibited tumor formation in normal intact females. The MTW9/PL cells retained their dual requirement for physiological levels of estrogens and prolactin for optimal tumor formation in W/Fu females as well as a requirement for physiological levels of thyroid hormones. Chromosomal analysis revealed a modal chromosome number of 62. A comparison of the cloned line with the parent line revealed > 11 hormone-related properties shared by the two lines. After 2 yr in culture, the MTW9/PL cells still retained the hormone-responsive growth characteristics of carcinogen-induced rat mammary tumors and normal rat mammary tissue. (35 refs.)

78-4766 **Growth Hormone Modulation of Murine Erythroleukemia Cell Growth In Vitro.** (Eng) Golde, D. W. (Div. Hematology-Oncology, Dept. Medicine, Univ. California Los Angeles Sch. Medicine, Los Angeles, CA, 90024); Bersch, N.; Li, C. H. *Proc Natl Acad Sci USA* 75(7): 3437-3439; 1978.

Friend leukemia virus-infected erythroleukemia cells were found to be responsive to growth hormone (somatotropin) in vitro. In a serum-free clonogenic assay, as little as 0.1 nanogram (ng)/ml of human growth hormone caused a prominent stimulation of cell proliferation. The peak activity of human growth hormone occurred at 200 ng/ml, resulting in a twofold increase in cloning. Human chorionic somatomammotropin and the Cys(Cam)^{53}-hGH(1-134) fragment of human growth hormone were also active, but a biologically inert oxidized human growth hormone had no growth-promoting effect in vitro. In addition, cell proliferation was stimulated by insulin, with peak potentiation occurring at 1 ng/ml, and by prolactin, which had a demonstrable stimulatory effect between 50 and 100 ng/ml. These observations indicate that growth hormone and related polypeptides have a direct effect on the in vitro proliferation of erythroleukemia cells in the absence of serum. The results confirm that there is a direct action of growth hormone on mammalian cells, and they suggest that pituitary hormones may affect leukemic cell growth. (26 refs.)

78-4767 **Warfarin Enantiomers, Anticoagulation, and Experimental Tumour Metastasis (Letter to Editor).** (Eng) Poggi, A. (Lab. Haemostasis and Thrombosis Res., Istituto di Ricerche Farmacologiche "Mario Negri", 20157 Milan, Italy); Mussoni, L.; Kornblihtt, L.; Ballabio, E.; de Gaetano, G.; Donati, M. B. *Lancet* 1(8056): 163-164; 1978.

The effect of sodium warfarin on Lewis lung carcinoma (3LL) induction in mice was investigated. Mice were treated with racemic sodium warfarin (RS) or its R(+) or S(-) enantiomers starting 2 days before im implantation of 3LL. Treatment was continued until the animals were killed. The prothrombin-complex activity was < 5% in animals treated with RS or S(-) warfarin, preparations endowed with anticoagulant activity, but it ranged from 90% to 110% in R(+) warfarin-treated and control mice. RS and S(-) warfarin, but not R(+) warfarin, significantly reduced both primary tumor and spontaneous lung metastases. Iv injection of 3LL cells induced an acute drop in blood platelets and other signs of acute disseminated intravascular coagulation. The drop in platelet count was prevented completely by RS or S(-) warfarin; R(+) warfarin was ineffective. The characteristic effects of these compounds also applied to the development of lung colonies, with tumor formation in R(+) warfarin-treated mice being the same as that in controls. These findings suggest that the antimetastatic effect of oral anticoagulants is not related directly to these compounds but requires impairment of vitamin K availability. (13 refs)

78-4768 **Regional Differences in Tumor Growth (Meeting Abstract).** (Eng) Auerbach, R. (Univ. Wisconsin, Madison, WI, 53706); Morrissey, L. W.; Kubai, L.; Sidky, Y. A. *Proc Am Assoc Cancer Res* 19: 177; 1978. (no refs)

78-4769 **Etiology of Infantile-Type Laryngeal Papillomas.** (Pol) Zakrzewski, A. (Klinika Laryngologiczna, Przybyszewskiego 49, 60-355 Poznan, Poland); Pruszewicz, A.; Kulczynski, B.; Citowicki, W.; Konczewska, H.; Topilko, A.; Sobieszczyk, S. *Otolaryngol Pol* 31(6): 641-646; 1977.

Hormonal, biochemical, and ultrastructural studies were made of 12 children aged 5-16 yr with infantile-type laryngeal papillomas. Serum gonadotropin, growth hormone, and Fe, Cu, Na, K, and Mg levels were measured along with Fe absorption and total binding capacity. The results of the hormonal investigations were within normal limits. However, the finding of a statistically significant decrease in serum Cu and Fe levels and the simultaneous demonstration of adenovirus particles (crystalline forms in the nuclei and B- and C-type particles crossing the cell membrane) are new contributions to the etiology of papillomas. (20 refs.)

78-4770 **Human Brain Tumor Transplantation into Nude Mice (Meeting Abstract).** (Eng) Shapiro, W. (Memorial Sloan-Kettering Cancer Center, New York City, NY, 10021); Basler, G.; Horten, B.; Chernkik, N.; Posner, J. *Proc Am Assoc Cancer Res* 19: 153; 1978. (no refs)

78-4771 **The Role of the Lungs and Liver in the Kinetics of Transplanted Lymphoid Leukemia L1210 Cells Labelled with Radiochromium ^{51}Cr.** (Eng) Skierski, J. (Dept. Biophysics and Biomathematics, Medical Center Postgraduate Education, Warsaw, Poland); Doroszewski, J. *Leuk Res* 1(4): 309-313; 1977.

The fate of a 0.1-ml inoculum of 10^7 ^{51}Cr-labeled L1210 leukemia cells administered either iv or via spleen puncture was investigated in inbred DBA-2/wf and BALB/c x DBA-2/wf/F_1 mice. The mice were decapitated either 5 or 90 min later. Five minutes after iv injection, 15% of the dose was found in the blood, 50% in the lungs, 15% in the liver, 0.3% in the spleen, and 2.15% in the kidneys. By 90 min postinjection, the radioactivity in the blood fell to <4% and that in the lungs to 22%. However, the radioactivity in the liver increased to 30% and that in the spleen to 2.25%; the radioactivity in the kidneys did not change. Five minutes after intraportal injection, approx 2% of the dose was present in the lungs, 65% in the liver, <7% in the blood, and approx 1% in the kidneys. By 90 min, the radioactivity in the liver fell to 35% and that in the lungs to 1%. The radioactivity in the kidneys increased to 3%; no change was noted in the blood. It is suggested that many cells taken up by the liver or passing through it undergo functional changes or are destroyed; cells taken up by the lungs are partially released undamaged and/or in the form of insoluble fragments. (14 refs)

78-4772 **Morphogenesis of Embryonal Gastric Transplants in Syngeneic Recipients of Different Age.** (Rus) Leitina, B. I. (Cancer Res. Center, Moscow, USSR); Aruin, L. I.; Zinzar, S. N.; Svet-Moldavsky, G. Ya.; Turusov, V. S. *Vestn Akad Med Nauk SSSR* (2): 50-59; 1978.

The effect of recipient age on the differentiation of transplanted stomach tissue was studied in BALB/c, DBA/2, and CBA mice. Two series of experiments were carried out. In the first series, minced stomach tissue from 18- to 20-day embryos was transplanted sc into syngeneic mature mice. The mice were sacrificed at varying times between 2-30 days posttransplantation. In the second series, a segment of the stomach fundus from 18- to 20-day embryos was transplanted sc into mature mice, 11- to 12-day old mice, 5- to 6-day-old mice and newborn (1-day-old) mice. The mice were sacrificed on day 50 after transplantation. In the first series, the transplanted stomach tissue showed progressive differentiation. In the second series, two types of cysts (with nodes 2-5 mm in diameter) were detected in the transplanted stomach segment. The newborn mice had only the undifferentiated type, but the rest of the mice had both undifferentiated and differentiated cysts. (14 refs)

78-4773 **Molecular Biological Aspects of the Problem of Human Genetics.** (Jpn) Sekiguchi, M. (Dept. Biology, Faculty Science, Kyushu Univ., Fukuoka, Japan). *Jpn J Hum Genet* 22(2/3): 137-143; 1977.

The use of phage T4 repair endonuclease on xeroderma pigmentosum (XP) cells with the aid of Sendai virus resulted in restoration of the repair capabilities of Groups A to E XP cells. This suggests that the incision step of excision repair in human cells is controlled by at least five genes, but only one gene is involved in the T4 system. (3 refs)

78-4777 **Histone Proteases and the Distribution of Retained Histones in Nuclei from Rat Ventral Prostate Cells Undergoing Hypertrophy or Hyperplasia.** (Eng) Kadohama, N. (Dept. Medicine, Div. C, Roswell Park Memorial Inst., Buffalo, NY); Shirley, M. A.; Anderson, K. M. *Int J Biochem* 8(8): 601-609; 1977.

The distribution of histones and histone proteases was studied in ventral prostate (VP) nuclei from normal rats, short-term (3-day, designated C_3), or long-term castrates (7-day, designated C_7), or castrates treated with testosterone propionate for 2 or 3 days (designated T_2 and T_3, respectively). C_3T_3 rats showed cellular hypertrophy (growth), C_7 marked prostate involution and cell death, and C_7T_2 cellular replication (hyperplasia). The distribution of histones in VP nuclei from normal rats, C_3, C_7, and C_3T_3 did not differ. VP nuclei from C_7T_2 contained less histone F2a2 than those of controls. The distribution of partially degraded histones in nuclear extracts from growing or dividing VP cells differed from each other and from their castrated controls, suggesting a differing distribution of histone proteases and/or modifications of F2a2. A functional role for histone proteases exhibiting apparent cell-cycle substrate specificity and/or modification of F2a2 was suggested. Limited selective proteolysis of histones in nuclei from regressing, hypertrophic, or hyperplastic prostate cells may be necessary to prepare chromatin for the subsequent molecular events (eg replication and reprogramming) required for these processes. 78-4779 **Colchicine and Cytochalasin B (CB) Effects on Random Movement, Spreading and Adhesion of Mouse Macrophages.** (Eng) Cheung, H. T. (Immunobiology Res. Center, Univ. Wisconsin, Madison, WI, 53706); Cantarow, W. D.; Sundharadas, G. *Exp Cell Res* 111(1): 95-103; 1978.

The role of microtubules and microfilaments in the control of random movement, spreading, and adhesion of peritoneal macrophages was investigated in C57BL/6 mouse peritoneal exudate cells (PEC) treated with colchicine and cytochalasin B (CB). Movement of complete Freund's adjuvant-induced PEC was substantially enhanced at colchicine concentrations $> 10^{-8}$ M. Max movement was observed in the concentration range 10^{-5}-10^{-4} M. The affected cells were mostly macrophages; it is not known why polymorphonuclear WBC did not also migrate. An increase in random movement of macrophages was also obtained with thioglycollate-induced PEC. Colchicine inhibited cell spreading down to a concentration of 10^{-10} M. At concentrations $> 10^{-8}$ M, there was a significant inhibition of adhesion that increased with increasing colchicine concentrations. CB inhibited the movement of peritoneal macrophages significantly at concentrations 10^{-7} M. At concentrations $> 10^{-6}$ M, CB caused a dramatic inhibition of spreading. There was a greater enhancement of migration in the presence of 10^{-8} M CB and $> 10^{-8}$ M colchicine than in the presence of colchicine alone. Furthermore, in the presence of 10^{-8} M CB, colchicine enhanced movement at concentrations as low as 10^{-12} M. These findings suggest a cooperative interaction between cytoplasmic microfilaments and microtubules in controlling cell movement, adhesion, and spreading. (23 refs)

78-4780 **Models for the Specific Adhesion of Cells to Cells.** (Eng) Bell, G. I. (Theoretical Biology and Biophysics Group, Theoretical Div., Univ. California's Los Alamos Scientific Lab., Los Alamos, NM, 87545). *Science* 200(4342): 618-627; 1978.

A theoretical framework for quantitatively assessing the role that bonds between cells or between cells and surfaces play in adhesion is proposed. The framework is applicable to adhesion mediated by reversible bonds between specific molecules such as antigen and antibody, lectin and carbohydrate, or enzyme and substrate. Based on a knowledge of the reaction rates for reactants in soln and of their diffusion constants both in soln and on membranes, it is possible to estimate reaction rates for membrane-bound reactants. Two models are developed for predicting the rate of bond formation between cells, and the predictions are compared with experimental findings. The force required to separate two cells is shown to be greater than the expected electrical forces between cells and of the same order of magnitude as the forces required to pull gangliosides out of the cell membrane. (71 refs)

78-4781 **Phosphate Metabolites in Lymphoid, Friend Erythroleukemia, and HeLa Cells Observed by High-Resolution ^{31}P Nuclear Magnetic Resonance.** (Eng) Navon, G. (Dept. Chemistry, Tel-Aviv Univ., Ramat-Aviv, Tel-Aviv, Israel); Navon, R.; Shulman, R. G.; Yamane, T. *Proc Natl Acad Sci USA* 75(2): 891-895; 1978.

High-resolution phosphorus-31 (^{31}P) nuclear magnetic resonance (NMR) spectra were observed for lymphoid, Friend erythroleukemia, and HeLa cells. Some phosphate metabolites [glycero(3)phosphocholine, phosphoethanolamine, phosphocholine, glycero(3)phosphoethanolamine, and creatine phosphate] were identified, and their concentrations were found to vary among the different cell lines. ATP/ADP ratios showed large variations among the cell lines. Although this ratio approached 1 in Friend and HeLa cells, high ATP concentrations were maintained in the lymphoid line cells. Phosphorylcholine and phosphorylethanolamine and their glyceryl esters were present in relatively high concentrations in the cells, but their ratios varied considerably. A high concentration of an unidentified diphosphodiester compound was observed in the Friend erythroleukemia and HeLa cells. No appreciable pH gradient across the cell membrane was observed in any of the cell lines, in contrast to the large pH gradient detected in microorganisms. It is concluded that the ^{31}P NMR spectra will make it possible to detect unexpected differences in the level of metabolites among cells from different sources as well as such differences between normal and transformed cells. (14 refs)

78-4782 **Lipid-Chemical Features of Human Gastric Cancerous, Polypous and Ulcerative Tissues.** (Eng) Nakazawa, I. (Third Dept. Internal Medicine, Tohoku Univ. Sch. Medicine, Sendai 980, Japan); Asaki, S.; Ito, S. *Tohoku J Exp Med* 123(4): 365-370; 1977.

The lipid levels of 14 cases of gastric cancer, 9 cases of gastric polyp, and 4 cases of gastric ulcer were studied to examine the biochemical differences between malignant and benign gastric tissue. Specimens of each lesion and the surrounding normal tissue were collected surgically. Part of each specimen was examined histologically, and the other part was subjected to lipid analyses by thin-layer and gas-liquid chromatography. The total lipid content was decreased in 71% of the gastric cancer cases and in 75% of the polyp and ulcer cases. The phospholipid fatty acid content was 83% lower in the cancerous lesions and 50% lower in the polypous lesions than in the surrounding normal tissue. Comparison of the phospholipid fatty acid composition in cancerous and polypous tissues indicated that the percentage of $C_{18:2}$ was decreased and that of $C_{20:4}$ was increased in the former as compared to the latter. The increase of $C_{20:4}$ in cancerous tissues could result in an increased fluidity of the cell membrane, and it might constitute at least one of the mechanisms involved in the malignant growth of cancerous gastric tissues. (10 refs)

78-4784 **Membrane Lipid Dynamics and Density Dependent Growth Control in Normal and Transformed Avian Cells.** (Eng) Nicolau, C. (Institut fur Strahlenchemie im Max-Planck-Institut fur Kohlenforschung, D4330 Mulheim a. d. Ruhr, W. Germany); Hildenbrand, K.; Reimann, A.; Johnson, S. M.; Vaheri, A.; Friis, R. R. *Exp Cell Res* 113(1): 63-73; 1978.

The membrane fluidity of normal chick embryo fibroblasts and normal Japanese quail fibroblasts and their Rous sarcoma virus (RSV)- and methylcholanthrene (MC) transformed counterparts was investigated by fluorescence polarization. Normal cells and their isolated plasma membranes showed significant changes in fluidity as a function of population density, but neither RSV- nor MC-transformed cells or their isolated plasma membranes showed this effect. Stimulation of growth by addition of calf serum to cultures of quiescent, density-inhibited normal cells was accompanied by increased membrane lipid fluidity that occurred <2 hr after stimulation. Neither sparse normal cells nor sparse or dense transformed cells showed any significant fluidity change in their membrane lipids following addition of serum. Enzyme and electron microscopic analysis of the ratios of different membrane types (plasma membrane:intracellular membrane) in each cell type showed that this ratio did not vary with respect to cell population density but that it was different between transformed and normal cells. It is concluded that the observed fluidity changes reflect organizational differences occurring as a function of population density in cell cultures that retain density-dependent growth control. (31 refs)

78-4785 **Role of Polyamines in the Regulation of Nuclear Division in Normal and Transformed Mammalian Cells (Meeting Abstract).** (Eng) Sunkara, P. S. (Dept. Developmental Therapeutics, Univ. 78-4787 **γ-Glutamyltranspeptidase Activity in Normal, Regenerating and Malignant Hepatocytes.** (Eng) Cheng, S. (Dept. Biochemistry, Univ. Southern California Sch. Medicine, Los Angeles, CA, 90033); Nassar, K.; Levy, D. *FEBS Lett* 85(2): 310-312; 1978.

To define factors affecting the activity of γ-glutamyltranspeptidase (GTP), the levels of this enzyme were investigated in quiescent hepatocytes, regenerating liver, Morris hepatoma 7777, hepatocytes in monolayer culture, and hepatoma tissue culture (HTC) cells in monolayer and spinner culture. Isolated normal hepatocytes from male Sprague-Dawley rats were found to possess very low enzyme activity. A comparison of the activity observed in whole cells with that in the corresponding cell homogenate indicated that 42% of the enzyme was associated with the cell surface. HTC cells exhibited a 150-fold increase in enzyme activity, with 52% being associated with the cell surface. Morris hepatoma 7777 also showed a large increase in enzyme activity. Normal (RL-34) and 4-nitroquinoline 1-oxide-treated (RL-34-HII) cells were not and only slightly tumorigenic, respectively. These cells exhibited a six- to sevenfold increase in enzyme activity and a cellular distribution, indicating a 70% and 50% surface association, respectively. The spontaneously transformed cell line, RLC C-1, expressed highly elevated levels, comparable to those of the HTC cell system, with 70% of the activity being associated with the cell surface. These results suggest that increased GTP activity correlates with the degree of tumorigenicity expressed by the cell line or tissue. Regenerating liver expressed low activity levels. A 2.5-fold increase in activity was observed after 12 hr, but it returned rapidly to a slightly elevated plateau. The comparatively low GTP activity in the regenerating liver suggests that the marked increases in its activity are characteristic of hepatocyte transformation and not of rapid cell proliferation. (17 refs)

78-4788 **Distribution of Glycoconjugates in Mouse Fibroblasts with Varying Degrees of Tumorigenicity.** (Eng) Winterbourne, D. J. (Macromolecular Biology Section, NCI, NIH, Bethesda, MD, 20014); Mora, P. T. *J Supramol Struct* 7(1): 91-100; 1977.

Glucosamine labeled glycoconjugates were compared in two clones and the parent embryonic mouse cell line. The two clones were at least 100-fold less tumorigenic than the parent cell line. Hyaluronic acid, heparan sulfate, and chondroitin sulfate as well as a complex mixture of glycopeptides were found in the medium, the trypsinate, and the trypsinized cells. The three cell lines had very similar in vitro growth properties, including their plating efficiency in viscous medium, and similar distributions of glycoconjugates throughout the culture. The only difference that correlated with higher tumorigenicity was a slightly higher labeling of hyaluronic acid relative to the other glycoconjugates in the parent cell line. The mechanism by which increased secretion of hyaluronic acid could benefit tumor growth is not clear, but it is possible that it could mask antigens, provide an appropriate extracellular matrix in which the cells could proliferate, or block lymphocyte proliferation. 78-4789 **Characterization of the L-Arabinose Sensitive Strain SV3 of *Salmonella typhimurium* and of L-Arabinose Resistant Mutants Selected in this Strain (Meeting Abstract).** (Eng) Pueyo, C. (Natl. Inst. Environmental Health Sciences, Research Triangle Park, NC); Lopez-Barea, J. *Genetics* 88(4, part 2, Suppl): s78-s79; 1978. (no refs)

78-4790 **Serum Antigens and Antibodies in the Diagnosis of Thyroid Cancer.** (Eng) DeGroot, L. J. (Thyroid Study Unit, Dept. Medicine, Univ. Chicago, Chicago, IL); Hoye, K.; Refetoff, S.; Van Herle, A. J.; Asteris, G. T.; Rochman, H. *J Clin Endocrinol Metab* 45(6): 1220-1223; 1977.

The sera of 80 patients with thyroid cancer and 275 patients with a history of radiation exposure were analyzed for carcinoembryonic antigen (CEA) and thyroglobulin (TG) by radioimmunoassay and for antithyroglobulin (TGHA) and antimicrosomal antibodies (MCHA) by RBC hemagglutination. Control values were obtained from a population of blood bank volunteers with an approx equal distribution of sex and age (19-35 yr). In the 275 irradiated patients, the number of positive results for each test was increased above that of controls, with the increase for TGHA and TG being significant ($p < 0.05$). However, patients with benign or malignant thyroid lesions in the irradiated group could not be screened on the basis of these test results. Thyroid cancer patients that lacked a history of x-ray exposure had more frequent positive responses for TGHA, MCHA, and CEA than cancer patients with such history. Among all tests and categories of patients, only the TG assay was distinctive in its association with thyroid cancer. Elevations of TG $>$ 300 nanograms/ml were found only in 4/4 Stage IV thyroid cancer patients, but in these patients the diagnosis was usually clinically obvious. In addition, 24/117 patients without cancer also had positive TG levels and, overall, 72% of the cancer patients had negative levels. (19 refs.)

78-4791 **Intracellular Magnesium Concentrations Found in Normal and Leukemic Human Leukocytes (Meeting Abstract).** (Eng) Brown, E. R. (Univ. Chicago Health Sciences, Chicago Medical Sch., Chicago, IL, 60612); Hazdra, J. J.; Callaghan, O. H. *Proc Am Assoc Cancer Res* 19: 172; 1978. (2 refs)

78-4792 **A Novel Quantitative Separation of Cr(III) from Numerous Metal Ions on β-Stannic Arsenate Thin Layers in DMSO-HCl Systems.** (Eng) Qureshi, M. (Chemistry Section, Z. H. Coll. Engineering and Technology, Aligarh Muslim Univ., Aligarh, India); Varshney, K. G.; Fatima, N. *Sep Sci Technol* 13(4): 321-333; 1978.

The use of β-stannic arsenate thin-layer chromatography and a dimethyl sulfoxide (DMSO) solvent system for the separation of Cr(III) from metal ions is described. The method is precise and accurate, and it can be applied for the quantitative separation of Cr(III) from mixtures containing Cu, Nb, Ta, Ce, Ni, Co, Al, Zn, Mn, Th, La, Cd, and Pt. The selective separation is a consequence of the kinetic inertness of Cr(III), the unique properties of DMSO, and the selectivity of the β-stannic arsenate layers. (19 refs)

78-4793 **Globin Messenger RNA Content in Hepatomas: A Test of Retrogenesis.** (Eng) Longenecker, J. P. (Dept. Biochemistry, Sch. General Studies, Australian Natl. Univ., P.O. Box 4, Canberra ACT 2600, Australia); Williams, J. F. *Cancer Lett* 4(1): 45-49; 1978.

The globin messenger RNA (mRNA) content of fetal, neonatal, and normal adult liver, of the transplantable Morris hepatoma 5123C, and of the host liver of animals carrying the tumor was measured in an attempt to identify an early developmental gene product under pretranslational control that could be used in clinical diagnosis. Hybridization experiments indicated that 90% of the fetal globin mRNA was lost 2 days after birth. Tumor and host liver extracts contained 4.13 and 2.38 times as much globin mRNA, respectively, as extracts of normal adult liver; however, the max hybridization was only 35% in all three tissues. This indicates that the reactive mRNA species from normal, host, and tumor extracts were the same and that they differed from the fetal and neonatal mRNA species. These results show that the gene for fetal globin mRNA is not reexpressed in the hepatoma and that it is not induced in the host liver. (15 refs)

78-4794 **Effect of Patulin on In Vitro Syntheses of RNA and Proteins.** (Fre) Hatey, F. (Institut de Recherches Scientifiques sur le Cancer, 94800 Villejuif, France); Moule, Y. *Ann Nutr Aliment* 31(4/5/6): 867-870; 1977.

The effects of patulin, a mycotoxin isolated from *Byssochlamis nivea*, on RNA transcription and translation was studied in vitro. Patulin inhibited RNA synthesis in isolated rat liver nuclei by 50-100% at a concentration of about 200 μg/ml. In transcriptional studies using RNA polymerases isolated from *Escherichia coli*, the mycotoxin apparently acted on RNA polymerase, and blocking occurred at the start of transcription. (11 refs)

78-4795 **Biochemical Analysis of Damage Induced in Yeast by Formaldehyde. II. Induction of Cross-Links Between DNA and Protein.** (Eng) Magana-Schwencke, N. (Fondation Curie-Institut du Radium, Biologie, 15, rue Georges Clemenceau, Batiment 110, 91405 - Orsay, France); Ekert, B. *Mutat Res* 51(1): 11-19; 1978.

The nature of the molecular damage caused by formaldehyde (FA) in the eucaryotic organism *Saccharomyces cerevisiae* was studied. A haploid strain of *S. cerevisiae*, N123 (a his$_1$), was used. ^{3}H-labeled cells were treated with 66 mM FA for 30 min in phosphate buffer, filtered, washed, and applied to neutral sucrose gradients. In the FA-treated cells, the DNA was strongly linked to a fast-sedimenting structure. Protoplasts were then incubated with 16.5-298 mM FA. A dose-effect relation was found for the induction of DNA-protein cross-links after FA treatment; no evidence for a threshold dose of FA was found. DNA extractability was measured after UV irradiation of protoplasts, and a dose-effect relation was found for the induction of cross-links. The equilibrium density-gradient centrifugation profile of DNA from FA-treated cells showed that a main nuclear peak at a density of 1,700 g/cm^3, which is found with untreated cells, had been displaced toward the lighter region of the gradient. This was due to the binding of DNA with a protein-containing material. (25 refs.)

78-4796 **Reverse Transcription of tRNA.** (Eng) Wittig, B. (Institut fur Molekularbiologie und Biochemie, Freie Universitat Berlin, Arnimallee 22, D-1000 Berlin

33, W. Germany); Wittig, S. *Nucleic Acids Res* 5(4): 1165-1178; 1978.

The 3′ terminus of transfer RNA (tRNA) was elongated enzymatically by an oligo(A) tail. A fragment of DNA polymerase I *Escherichia coli* was used in the presence of manganese to phase and synthesize a cleavable primer at the oligo-(A)-tRNA template. When the three-dimensional structure of oligo(A)-tRNA was unfolded under conditions in which the primer still hybridized at the oligo(A) tail, the DNA polymerase I fragment transcribed oligo(A)-tRNA into DNA. Reverse transcription was slowed and its fidelity was suspended by the 1-methyladenine in oligo(A)-tRNA-Phe (yeast). The reaction was stopped by the highly modified Y base present in this template. Approx full-length transcripts can be obtained from oligo(A)-tRNA$_3$-Gly (*E. coli*). The transcription products were characterized by sequence analysis. (28 refs)

78-4797 **Human Uracil DNA N-Glycosidase: Studies in Normal and Repair Defective Cultured Fibroblasts.** (Eng) Kuhnlein, U. (Dept. Biochemistry, Univ. California, Berkeley, CA, 94720); Lee, B.; Linn, S. *Nucleic Acids Res* 5(1): 117-125; 1978.

Uracil DNA N-glycosidase activity was analyzed in extracts of human fibroblasts from normal subjects, those with xeroderma pigmentosum (XP), and a subject with ataxia telangiectasia (AT). This enzyme is involved in the excision of uracil from DNA. Cell lines representative of complementation Groups A and D of XP and AT had almost the same level of activity as the normal cells. In contrast, cells from two XP variants (XP4BE and XP13BE) had roughly half the normal level of activity, and cells from the heterozygous mother of XP4BE had an intermediate level of activity. In spite of these quantitative differences, there were no systematic alterations in reaction characteristics, apparent Km for the substrate, or purification characteristics for the enzyme for any of the lines. A causal relationship, if any, between uracil DNA N-glycosidase levels and repair deficiency diseases is concluded to be equivocal. (25 refs)

78-4798 **Extracellular DNA Polymerase from Breast Cyst Fluids and Derived Cell Cultures (Meeting Abstract).** (Eng) Witkin, S. S. (Memorial Sloan-Kettering Cancer Center, New York, NY, 10021); Borenfreund, E.; Bendich, A.; Fleisher, M.; Schwartz, M. K. *Proc Am Assoc Cancer Res* 19: 175; 1978. (no refs)

78-4799 **Invasive Locomotory Behavior Between Malignant Human Melanoma Cells and Normal Fibroblasts Filmed in Vitro.** (Eng) Stephenson, E. M. (Zoology Building, A08, Univ. Sydney, Sydney 2006, Australia); Stephenson, N. G. *J Cell Sci* 32: 389-418; 1978.

The relative invasive capacities of human malignant melanoma (MM96) cells and normal adult human skin fibroblasts (HSF) were compared with those of a standard population of chick heart fibroblasts (CHF). The different cell types were confronted in pairs and filmed as they moved outward and eventually met in a situation in which each could potentially invade the other. Replicate cultures were fixed and stained 24 to 40 hr after junction. MM96 cells invaded the CHF population but eventually encountered moderate obstruction. Invasion was mainly by oriented movement between two successive pairs of chick cells. Contact paralysis of ruffling of MM96 was not seen. HSF did not invade the CHF; they were contact-inhibited by the latter and typically reversed their direction of movement. MM96 cells invaded the HSF without obstruction, using several different pathways for locomotory invasion, including overlapping. CHF and HSF were contact-inhibited by leading-edge collisions with MM96 cells. Fibroblast invasion of MM96 was by underlapping of orthogonally oriented, bipolar melanocytes or dendritic processes. HSF were less obstructed than CHF during invasion of MM96. Initiation of invasion of HSF by CHF was apparently orientation-dependent and was assisted by the alignment, morphology, and contact-mediated withdrawal of the HSF. Heterologous contact inhibition did not appear defective for either cell type. In all confrontations involving both malignant and nonmalignant cells, the extent and pattern of invasion could be related to apparent deficiencies in heterologous contact inhibition of locomotion. (21 refs.)

78-4800 **Personality Structures of Breast Cancer Patients (IV). Depression and Cancer: A Comparison.** (Spa) Lerer, S. B. (Departmento de Psiquiatria, Facultad de Medicina, Univ. Javeriana, Bogota, Colombia); Silva, J. L.; Garcia, D.; Gomez, R.; Mendez, J. L. *Rev Colomb Psiquiatria* 6(3): 255-273; 1977.

Psychological studies were performed on 20 women with adenocarcinoma of the breast and 20 women with neurotic depression and hyperchondria. Compared with the neurotic depressives, the cancer patients were significantly more repressed and less assertive. They also had less capacity for play, socializatioin, and interpersonal relationships. Although personal losses triggered psychosomatic symptoms in both groups, the cancer patients derived less secondary gain from their symptoms. The possibility that a submissive attitude can adversely effect a cancer patient's prognosis is discussed. (21 refs)

Subject Index

Abdominal Neoplasms
- Neuroblastoma
  - Virus, Polyoma, JC, 78-4476

Abnormalities
- Ethane, 2-Bromo-2-chloro-1,1,1-trifluoro-
  - Occupational Hazard, 78-4710
- Neoplasms
  - Child, Review, 78-4213

Acetamide, *N*-(Acetyloxy)-*N*-fluoren-2-yl-
- Caffeine
  - Azaguanine/Thioguanine Resistance, 78-4289
  - Cells, Cultured, 78-4289
  - Mutagenic Activity, 78-4289
- Mutagenic Activity
  - Azaguanine/Thioguanine Resistance, 78-4289

Acetamide, *N*-Fluoren-2-yl-
- Antigens
  - Hydro-Lyases, 78-4284
  - Precancerous Conditions, 78-4284
- Fluorene, 2-Azido-
  - Carcinogenic Metabolite, 78-4282
- Hepatoma
  - Aldehyde Oxidoreductases, 78-4287
  - Enzymatic Activity, 78-4286
  - Hydro-Lyases, 78-4284
  - Viral Proteins, 78-4530
  - Virus, C-Type RNA Tumor, 78-4530
- Liver Neoplasms
  - Hyperplasia, 78-4579
- Polyamines
  - Liver, Rat, 78-4283
- RNA, Transfer, Methyltransferases
  - Liver, Rat, 78-4283
  - Polyamines, 78-4283
  - Sex Factors, 78-4283
- Sex Factors
  - Metabolism, Liver, 78-4283
- Urea, Hydroxy-
  - Hepatocytes, 78-4285

Acetamide, 2-Iodo-
- Stomach Neoplasms
  - Guanidine, 1-Methyl-3-nitro-1-nitroso-, 78-4313
  - Peptic Ulcer, 78-4313

Acetanilide, 4-Butoxy-4′-styryl-
- Microsomes, Liver
  - Metabolism, 78-4316

Acetanilide, 4′-Styryl-
- Microsomes, Liver
  - Alkoxy Substituents, 78-4316

Acetanilide, 4′-Styryl-4-ethoxy-
- Microsomes, Liver
  - Metabolism, 78-4316

Acetanilide, 4′-Styryl-4-methoxy-
- Microsomes, Liver
  - Metabolism, 78-4316

Acetanilide, 4′-Styryl-4-propoxy-
- Microsomes, Liver
  - Metabolism, 78-4316

Acetic Acid, ((Carboxymethylimino)bis(ethylenenitrilo))tetra-
- Plutonium
  - Body Burden, Mathematical Model, 78-4356
  - Inhalation and Excretion, 78-4356

Acetic Acid, Ethylnitrosaminoethyl Ester
- Enzyme Activation
  - Carcinogenic Acitivty, Review, 78-4233

Acetic Acid, Iodo-
- Mammary Neoplasms, Experimental
  - Transplantation Immunology, 78-4573

Acetic Acid, Mercapto-
- Macrophages
  - Tumor Cytotoxicity, 78-4547

Acetohydroxamic Acid, *N*-Fluoren-2-yl-
- Ascorbic Acid
  - Mutagenic Activity, 78-4288
- Barbituric Acid, 5-Ethyl-5-phenyl-
  - Ames Test, 78-4288
- Cholanthrene, 3-Methyl-
  - Ames Test, 78-4288
- *p*-Cresol, 2,6-Di-*tert*-butyl-
  - Mutagenic Activity, 78-4288
- Enzyme Activation
  - Carcinogenic Acitivty, Review, 78-4233
  - Mutagenic Activity, 78-4288
- Fluorene, 2-Azido-
  - Ultraviolet Rays, 78-4282
- Mammary Neoplasms, Experimental
  - Neuraminidase, 78-4589
- Microsomes
  - Ames Test, 78-4288
  - Deacetylation, 78-4288
  - Mutagenic Activity, 78-4288
- Phosphoric Acid, Diethyl-, *p*-Nitrophenyl Ester
  - Ames Test, 78-4288
  - Enzyme Activation, 78-4288
- RNA Polymerase
  - Liver, Rat, 78-4281
  - Nucleotide Incorporation, 78-4281
- Ultraviolet Rays
  - Cell Transformation, Neoplastic, 78-4282

Achlorhydria
- Stomach Neoplasms
  - Precancerous Conditions, Review, 78-4211

Acid Phosphatase
- Leukemia, Hairy Cell
  - Cells, Cultured, 78-4552

Acridine, 9-Amino-
- HeLa Cells
  - DNA Repair, 78-4306

Acridine, 3,6-Diamino-
- Amino Acids
  - DNA, Binding, 78-4376
- Fluorescence
  - Co-carcinogenic Activity, 78-4502
- Light
  - Free Radicals, 78-4376
- Sulfur
  - DNA, Binding, 78-4376
  - Free Radicals, 78-4376

Acridine, 3,6-Diamino- (cont'd)
- Virus, Herpes Simplex 2
  - Co-carcinogenic Activity, 78-4502
  - DNA Replication, 78-4502
  - Fluorescence, 78-4502
  - Thymidine Kinase, 78-4502
  - Ultraviolet Rays, 78-4502
  - Virus Replication, 78-4502

Actin
- Mammary Neoplasms, Experimental
  - Cells, Cultured, 78-4663
- Virus, Avian Myelocytomatosis
  - Cell Transformation, Neoplastic, 78-4386
- Virus, Rous Sarcoma
  - Cell Transformation, Neoplastic, 78-4386

Actinomycin D
- Hepatoma
  - Lipids, 78-4577
- Virus, C-Type RNA Tumor
  - Virus Activation, 78-4453

Adenocarcinoma
- Bone Neoplasms
  - Neoplasm Metastasis, 78-4654
  - Tannic Acid, 78-4737
- Colonic Neoplasms
  - Carcinoembryonic Antigen, 78-4688
  - Cell Cycle Kinetics, 78-4688
  - Hydrazine, 1,2-Dimethyl-, 78-4278
  - Transplantation, Heterologous, 78-4688
- Duodenal Neoplasms
  - Guanidine, 1-Methyl-3-nitro-1-nitroso-, 78-4313
- Esophageal Neoplasms
  - Epidemiology, India, 78-4740
- Gynecologic Neoplasms
  - Urea, Methyl Nitroso-, 78-4309
- Intestinal Neoplasms
  - Age Factors, 78-4692
  - Epidemiology, Japan, 78-4692
  - Occupational Hazard, 78-4690
- Kidney Neoplasms
  - Epidemiology, Frog, 78-4751
- Lung Neoplasms
  - Cell Cycle Kinetics, 78-4682
  - Hybrid Cells, 78-4668
- Mammary Neoplasms, Experimental
  - Cell Agglutination, 78-4663
  - Glutaraldehyde, 78-4573
  - Neoplasm Metastasis, 78-4650
  - Surface Properties, 78-4663
- Stomach Neoplasms
  - Guanidine, 1-Methyl-3-nitro-1-nitroso-, 78-4313
- Thyroid Neoplasms
  - Epidemiology, Kenya, 78-4721
  - Goiter, Endemic, 78-4721
  - Thyrotropin, 78-4719
- Transplantation, Heterologous
  - Mouse, Nude, 78-4564
- Vaginal Neoplasms
  - 4,4′-Stilbenediol, *α,α′*-Diethyl-, 78-4228

Adenofibroma
- Mammary Neoplasms, Experimental
  - Precancerous Conditions, 78-4665

Adenoma
- Lung Neoplasms
  - Benzo(a)pyrene, 78-4340

Adenoma (cont'd)
  - Benzo(a)pyrene, 7,8-Dihydro-7,8-dihydroxy- 78-4340
  - Benzo(a)pyrene, 7,8-Dihydroxy-9,10-oxy-7,8,9,10-tetrahydro-, 78-4340
- Mammary Neoplasms, Experimental
  - Precancerous Conditions, 78-4665
- Parathyroid Neoplasms
  - APUD Cells, 78-4662
  - Radiation, Ionizing, 78-4370
  - Ultrastructural Study, 78-4662
- Stomach Neoplasms
  - Guanidine, 1-Methyl-3-nitro-1-nitroso-, 78-4313

Adenosine Cyclic 3′,5′ Monophosphate
- Mammary Neoplasms, Experimental
  - Transplantation Immunology, 78-4573
- 12-*O*-Tetradecanoylphorbol-13-acetate
  - Epidermis, Mouse, 78-4312

Adenosine Monophosphate
- Virus, Picorna
  - Adenosine Triphosphate, 3′-Deoxy-, 78-4515
- Virus, Polio
  - Adenosine Triphosphate, 3′-Deoxy-, 78-4515
- Virus, Rhino
  - Adenosine Triphosphate, 3′-Deoxy-, 78-4515

Adenosine Triphosphatase
- Benzo(a)pyrene
  - Mutagenic Activity, 78-4341
- Erythroleukemia
  - Nuclear Magnetic Resonance Spectra, 78-4781
- Guanidine, 1-Methyl-3-nitro-1-nitroso-
  - Mutagenic Activity, 78-4341
- HeLa Cells
  - Nuclear Magnetic Resonance Spectra, 78-4781
- Ultraviolet Rays
  - Mutagenic Activity, 78-4363

Adenosine Triphosphate
- Leukemia, Lymphoblastic
  - Magnesium, 78-4791
- Leukemia, Myelocytic
  - Magnesium, 78-4791

Adenosine Triphosphate, 3′-Deoxy-
- Virus, Picorna
  - Adenosine Monophosphate, 78-4515
  - Guanine Nucleotides, 78-4515
  - RNA Replication, 78-4515
- Virus, Polio
  - Adenosine Monophosphate, 78-4515
  - Guanine Nucleotides, 78-4515
  - RNA Replication, 78-4515
- Virus, Rhino
  - Adenosine Monophosphate, 78-4515
  - Guanine Nucleotides, 78-4515
  - RNA Replication, 78-4515

***S*-Adenosylmethionine Decarboxylase**
- Carcinoma, Ehrlich Tumor
  - Neoplasm Transplantation, 78-4764

Adrenal Cortex Hormones
- Cervix Neoplasms
  - Age Factors, Metabolism, 78-4698
  - Epidemiology, 78-4698
- Cholanthrene, 3-Methyl-
  - Dose-Response Study, Mouse, 78-4606
  - Immunosuppression, 78-4606

drenal Gland Neoplasms
- Aging
  - Strain Difference, Mouse, 78-4757
- Carcinoma
  - Age Factors, Mouse, 78-4523
- Genetics
  - Case Report, 78-4646
- Virus, C-Type RNA Tumor
  - Ovariectomy, Mouse, 78-4523

driamycin
- Hepatoma
  - Lipids, 78-4577

flatoxin B1
- Aflatoxin B1, 2,3-Dihydro-2,3-dihydroxy-
  - Carcinogenic Metabolite, 78-4264
- Alpha Fetoproteins
  - Binding, 78-4259
  - Fluorescence Spectra, 78-4259
- α-Amanitine
  - RNA Polymerase, 78-4262
- Dexamethasone
  - Cytotoxicity, 78-4579
- *Drosophila melanogaster*
  - Mutagenic Activity, 78-4258
- Hepatoma
  - Histological Study, Trout, 78-4263
  - Induction, Trout Embryo, 78-4263
- Hyperplasia
  - Cell Differentiation, Liver, 78-4579
- Lipids
  - Liver, Rat, 78-4260
- Liver Neoplasms
  - Cytotoxicity, 78-4579
  - Hyperplasia, 78-4579
- Microsomes, Liver
  - Carcinogenic Metabolite, 78-4264
  - Diet, 78-4261
  - Mutagenic Activity, 78-4261
- Nucleic Acids
  - Mutagenic Activity, 78-4258
- Proteins
  - Liver, Rat, 78-4260
  - Mitochondria, Liver, 78-4260
- RNA Polymerase
  - Chromatin Template Activity, 78-4262
  - Liver, Rat, 78-4262
- RNA Replication
  - Liver, Rat, 78-4262
- Serum Albumin, Bovine
  - Binding, 78-4259
- Sex Chromosomes
  - Mutagenic Activity, 78-4258
- Urea, Hydroxy-
  - Hepatocytes, 78-4285

flatoxin B2
- HeLa Cells
  - DNA Repair, 78-4306

flatoxin B1 2,3-Dichloride
- *Drosophila melanogaster*
  - Mutagenic Activity, 78-4258
- Nucleic Acids
  - Mutagenic Activity, 78-4258
- Sex Chromosomes
  - Mutagenic Activity, 78-4258

Aflatoxin B1, 2,3-Dihydro-2,3-dihydroxy-
- Aflatoxin B1
  - Carcinogenic Metabolite, 78-4264
- Cytochrome P-450
  - Microsomes, Liver, 78-4264
- NADP
  - Microsomes, Liver, 78-4264

Aflatoxin G1
- Lipids
  - Liver, Rat, 78-4260
- Proteins
  - Liver, Rat, 78-4260
  - Mitochondria, Liver, 78-4260

Aflatoxin M1
- Glycogen
  - Liver, Rat, 78-4260
- Lipids
  - Liver, Rat, 78-4260
- Proteins
  - Liver, Rat, 78-4260
  - Mitochondria, Liver, 78-4260

Aging
- Adrenal Gland Neoplasms
  - Strain Difference, Mouse, 78-4757
- Cell Transformation, Neoplastic
  - Strain Difference, Mouse, 78-4757
- Kidney Diseases
  - Strain Difference, Mouse, 78-4757
- Lung Neoplasms
  - Strain Difference, Mouse, 78-4757
- Sarcoma, Reticulum Cell
  - Strain Difference, Mouse, 78-4757
- Uterine Neoplasms
  - Strain Difference, Mouse, 78-4757

Air Pollution
- Benz(a)anthracene, 7,12-Dimethyl-
  - Carcinogenic Activity, 78-4344
- Benzo(a)pyrene
  - Carcinogenic Activity, 78-4344
- Bladder Neoplasms
  - Epidemiology, Australia, 78-4731
- Carcinoembryonic Antigen
  - Health Effects, 78-4750
- Carcinogen, Chemical
  - Co-carcinogenic Activity, 78-4345
  - Dose-Response Study, 78-4345
  - Threshold Values, Review, 78-4236
- Complement
  - Health Effects, 78-4750
- Dibenz(a,h)anthracene
  - Carcinogenic Activity, 78-4344
- Hemoglobins
  - Health Effects, 78-4750
- Lung Neoplasms
  - Dose-Response Study, Review, 78-4223
  - Epidemiology, 78-4695, 78-4750
  - Epidemiology, Review, 78-4221, 78-4222, 78-4223
- Respiratory System
  - Health Effects, 78-4750
- Smoking
  - Co-carcinogenic Activity, Review, 78-4222, 78-4223
  - Epidemiology, Review, 78-4221

Alanine, 3-(*p*-(Bis(2-chloroethyl)amino)phenyl)-
- Antineoplastic Agents
